INDEX TO VOLUME CX.

Abbe, R. Dupuytren's finger contraction, 419.

Abbott, S. L. Acute eczema in pregnancy, 276.

Abbott, L. F. The milk supply of Boston, and the benefit to be derived from spaying cows, 317, 352.

Abbott, S. W. Modern legislation relative to adulteration of food and drugs, 241, 253.

Abdominal Surgery. Two cases of abdominal section to discover the cause of intestinal obstruction, Homans, J., 145, 156; report of cases treated in Ward XIX., Royal Infirmary, Edinburgh, 619.

Abortion. Retained placenta of abortion, with hæmorrhage, Brown, M. L., 573.

Abscess. Recent methods of treating cold abscesses, Billroth, 190.

Actinomycosis of the peritoneum and abdominal organs in man, 259; a case of actinomycosis in a heifer, Whitney, W. F., 532, 545.

Addison's Disease. Howe, O. T., 181.

Adirondacks. The preservation of the Adirondacks, 114.

Adulteration of Food and Drugs. Modern legislation, Abbott, S. W., 241, 253; adulteration of food and drugs, Colcord, S. M., Canning, H., Markoe, G. F. H., Bartlet, W. W., Davenport, B. F., Durkee, W. C., 273; pettifogging by the drug adulterators, 286; adulterated drugs, 358; further legislation to prevent the adulteration of food and drugs, 378.

Albumen. The detection of albumen in urine, Fowler, G. B., 299.

Albuminuria. Nitro-glycerine and the chloride of gold and sodium in the treatment of albuminuria, Bartholow, R., 32; albuminuria, Griswold, G., 538; physiological albuminuria, Chateaubourg, 550.

Amaurosis. A case of sudden amaurosis, recovery, Derby, H., 126.

Ammonia. Inhalation of ammonia, Swan, C. W., 497.

Anæsthesia. Ether administered by the rectum, 405; etherization by the rectum, Post, A., 442, 451; some of the dangers and disadvantages of anæsthesia, Cheever, D. W., 509.

Anatomy. Recent progress in anatomy, Dwight, T., 225; the differences in form of the adult head, Dalton, J. C., 229; lecture in the course on Topographical Anatomy, Dwight, T., 505; modern methods in anatomy, Dwight, T., 585.

Aneurism of the thoracic aorta, O'Leary, C., 37; aneurism of the ascending aorta, Blake, J. G., 61; abdominal aneurism, Stevens, E. H., 61; atheroma, dilatation and aneurism of the aorta, etc., Musser, J. H., 87.

Animals. Perception of musical notes in animals, 561.

Annus Medicus incipiens, 18.

Antiseptics in the New York Hospital, 106.

Appendix. Colloid cancer of the appendix vermiformis, Draper, F. W., 131.

Arteries. The healing of arteries after ligature, Warren, J. C., 418.

Asch, M. J. A case of ecchondrosis of the larynx, 511.

Bacillus. Pathological and practical relations of the bacillus tuberculosis, Flint, A., 108; a new method for the detection of the bacillus tuberculosis, Hartsell, 166; Hartsell's method for staining the tubercle bacillus, Ernst, H. C., 213; the diagnostic value of the discovery of the "bacillus tuberculosis" in sputum, 498; the tubercle bacillus, 618.

Baker, H. A. An improved appliance in the physiological treatment of cleft palate, 127, 134.

Baker, W. H. A case showing the effects of hot water on papillary tumors of the bladder, 593.

Baltimore. Letter from Baltimore, 237.

Barnes, H. J. Sewage systems and the epuration of sewage by irrigation and agriculture, 577, 603, 609.

Bartholow, R. Nitro-glycerine and the chloride of gold and sodium in the treatment of albuminuria, 32; what is meant by nervous prostration? 58, 63.

Berlin Polyclinic, 834.

Bibliography. Agnew, D. H., The Principles and Practice of Surgery, Vol. III., 160; Allen, H., A System of Human Anatomy, including its Medical and Surgical Relations, 232; Bloxam, C. L., Chemistry: Inorganic and Organic, with Experiments, 593; Brown, F. H., The Medical Register for New England, 474; Browne, L., and Behnke, E., Voice, Song and Speech, 232; Browning, W., The Veins of the Brain and its Envelopes: Their Anatomy and Bearing on the Intra-Cranial Circulation, 508; Bruce-Clarke, G. W., and Lockwood, C. B., The Dissector's Manual, 64; Bruck, L., The Australasian Medical Directory and Hand-Book, 184; Bumstead, F. J., and Taylor, R. W., The Physiology and Treatment of Venereal Diseases, 328; Butlin, H. T., Malignant Disease (Sarcoma and Carcinoma) of the Larynx, 567; Chapman, H. C., History of the Discovery of the Circulation of the Blood, 518; Coats, J., A Manual of Pathology, 400; Cullingworth, C. J., A Short Manual for Monthly Nurses, 377; Duncan, J. M., on Sterility in Woman, 209; Garnier, P., Dictionnaire Annuel des Progrès des Sciences et Institutions Médicales, 568; Gerhard, W. P., Hints on the Drainage and Sewerage of Dwellings, 257; Gowers, W. R., The Diagnosis of Diseases of the Spinal Cord, 209; Gradle, H., Bacteria and the Germ Theory of Disease, 328; Gynecological Society, American, Transactions, 1882, 111; Gynecological Society, American, Transactions, 1883, 279; Hamilton, A. McL., A Manual of Medical Jurisprudence, with Special Reference to Diseases and Injuries of the Nervous System, 377; Hutchison, J. C., The Laws of Health, 617; Iowa, Sixth Biennial Report of the State Board of Health for the Year ending June 30, 1883, 520; King, A. F. A., A Manual of Obstetrics, 424; Magnin, A., and Sternberg, G. M., Bacteria, 280; Mann, E. C., A Manual of Psychological Medicine and Allied Nervous Diseases, 137; Martin, H. N., and Moale, W. A., Hand-book of Vertebrate Dissection, 618; Massachusetts General Hospital, and McLean Asylum, Seventieth Annual Report, 376; Michener, E., Hand-Book of Eclampsia, 257; Minnesota, Ninth Report of the State Board of Health, 424; National Board of Health, Report for the Year 1882-1883, 41; New York and Brooklyn Formulary of Unofficinal Preparations, 545; Oldberg, O., and Wall, O. A., A Companion to the United States Pharmacopœia, 520; Parker, T. J., A Course of Instruction in Zöötomy (Vertebrata), 518; Parkes, E. A., A Manual of Practical Hygiene, 400; Porritt, N., Intra-thoracic Effusion, 112; Power, H., Elements of Human Physiology, 184; Quinan, J. R., Medical Annals of Baltimore from 1608 to 1880, 519; Remsen, J., Principles of Practical Chemistry, 545; Richardson, B. W., The Field of Disease, 519; Ringer, S., A Handbook of Therapeutics, 545; Seguin, E. C., Opera Minora, 279; Semple, A., The Diseases of Children, 520; Shirk, J. K., Female Hygiene and Female Diseases, 568; South Carolina, The Fourth Annual Report of the State Board of Health, 160; Tidy, C. M., Legal Medicine, 518; Treves, F., Surgical Applied Anatomy, 39; Tuke, D. H., Illustrations of the Influence of Mind upon the Body in Health and Disease, Designed to Elucidate the Action of the Imagination, 423; Wells, J. S., A Treatise on the Diseases of the Eye, 112; Wickes, S., Sepulture; Its History, Methods, and Sanitary Requisites, 520; Woodhead, J. S., Practical Pathology, 280.

Billroth. Recent methods of treating cold abscesses, 190.

Biography. Allen, A. N., 168, 288; Balfour, J. H., 240; Bullock, O., 264, 640; Campbell, W. H., 422; Chalmers, T. C., 571; Clark, J. L., 144; Dresser, S. P., 72; DuBois, H. A., 92; Dumas, J. B., 528; Ellis, C., 70, 151, 166, 186; Engelmann, G., 240; Fowler, E. O., 504; Gilman, J. T., 92; Gross, S. D., 465, 532; Harris, E., 141; Hildreth, C. H., 504; Holt, A. F., 46; Hooker, G., 288; Jewett, J. J., 144; Jewett, P. A., 384; Lawrence, F. P., 21; Lawrence, G. C., 70, 168; Livingston, B., 188; Lord, C. M., 264; Parker, W., 427; Perry, T. W., 70, 72, 384, 616; Roberts, M., 240; Sabin, H. L., 216, 288; Whipple, S. M., 115; Yandell, L. P., 312.

Blake, C. J. Perception of musical notes in animals, 561.

Blake, J. G. Aneurism of ascending aorta, 61; dermoid cyst of the right ovary, 62; the medical treatment of uterine fibroids, 564; puerperal convulsions, 565.

Blistering. Topical cardiac blistering in the treatment of acute rheumatism, Parks, N. O. D., 393.

Blood-Poisoning following surgical operations, Wheeler, W. G., 271.

Bolles, W. P. Report on Materia Medica, 200; peculiar case of valvular disease of the heart, 348.

Bone. Osteo-myelitis of tibia, Wilson, C. M., 136; brittle bones, Graham, D., 467.

Borax. Pathological conditions of the skin following the internal use of borax, Wigglesworth, E., 404.

Bosworth, F. H. The clinical significance of fibrinous exudation upon the mucous membrane of the upper air passages, 491.

Bowditch, H. I. Letter on Dr. Calvin Ellis, 152; chronic retention of urine, 349.

Bowditch, H. P. Methods of instruction and research in physiology, 584.

Bowdoin Medical College. Graduating exercises, 549; Medical Alumni Association, 549.

Bradford, E. H. Excision in hip disease; are its prognosis and its results better than those of a spontaneous cure, 7; a successful case of amputation at the hip-joint, 257; on the use of force in the treatment of resistant club-foot, 265; report on orthopædic surgery, 394.

Brannan, J. W. The treatment of retained secundines after abortion, 147.

Breast. Section of fibroma mammæ, MacConnell, W. G., 38; case of mammary cancer, Green, C. M., 59.

Brockway, C. H. Thrombosis and the conditions which favor its development, 56.

Broughton, H. W. "Infectious" pneumonia; gangrene of lung; fetid empyema; recovery, 172.

Brown, D. An acephalous monster, 539.

Brown, M. L. Retained placenta of abortion, with hæmorrhage, 573.

Browne, W. T. Plaster supports, 269.

Bruen, E. T. History of a case of perihepatic abscess, 412.

Bubonocele. Pressure in the treatment of bubonocele, Petersen, O., 5.

Burge, W. J. Malignant disease of the bladder, 304.

Burrell, H. L. Tumor of the uterus, 383.

Cabaniss, T. T. Contagiousness of typhoid, 524.

Cabot, A. T. A new hip splint, 6; multiple calculi in the bladder, 398.

Cæsarean Section as performed by savages, 450.

Calculus. Salivary calculi of the right sub-maxillary gland, Cox, J. B., 35; multiple calculi in the bladder, Cabot, A. T., 398.

California. Some observations on Southern California and Colorado, Davenport, F. H., 554.

Cancer. Colloid cancer of the appendix vermiformis, Draper, F. W., 131.

Carcinoma. Colloid carcinoma, Hearn, J., 565.

Catarrh. Chronic nasal catarrh; removal of hypertrophied tissue, Knight, F. I., 132.

Ceilings. High and low ceilings, 286.

Cephalhæmatoma, Haven, H. C., 184.

Cerebral Localizations, Hurd, E. P., 561.

Cerebro-spinal Meningitis, five cases, Mason, A. L., 121, 132; some suggestions upon cerebro-spinal meningitis, Davis, H. G., 262.

Chadwick, J. R. Sea voyages and amenorrhœa, 448.

Channing, W. Recent progress in the construction of insane hospitals, and management of the insane, 295, 321.

Chateaubourg. Physiological albuminuria, 550.

Cheever, D. W. Some of the dangers and disadvantages of anæsthesia, 509.

Chemistry. The clinical examination of diabetic urine by Duhomme's test, Hurd, E. P., 21; report on medical chemistry, Hills, W. B., 130.

Children. Case resembling infantile paralysis caused by improper food, Minot, F., 275; the hygiene of study, 305; recent progress in diseases of children, Rotch, T. M., 365.

Children's Hospital, Boston, 46.

Chias. Cremation in China, 140.

Choral. An over-dose of chloral, Reynolds, J. P., 151.

Cholera. "Precautions against cholera," 165; reports on cholera, Surgeon-General Hunter and Dr. Robert Koch, 258.

Circulatory System. Enormous hypertrophy of the heart, Dulles, C. W., 16; refusion in carbonic oxide poisoning, Halsted, W. S., 22; paracentesis of the pericardium, Macdonald, J. W., 22; aneurism of the thoracic aorta, O'Leary, C., 37; calcified pericardium, double mitral disease, 37; thrombosis, and the conditions which favor its development, Brockway, C. H., 56; aneurism of the ascending aorta, Blake, J. G., 61; abdominal aneurism, Stevens, E. H., 61; atheroma, dilatation and aneurism of the aorta, etc., Musser, J. H., 87; recent progress in the treatment of thoracic disease, Shattuck, F. C., 174; topical cardiac blistering in the treatment of acute rheumatism, Parks, N. O'D., 303; peculiar case of valvular disease of the heart, Bolles, W. P., 348; rupture of one of the aortic valves during severe muscular strain, 372; spontaneous phlebitis, Fifield, W. C. B., 397; probable transfixion of the heart, with recovery, 406; the healing of arteries after ligature, Warren, J. C., 418; umbilical hæmorrhage, Cobb, J. S., 422; cardiac hæmorrhage, Fitz, R. H., 544; umbilical hæmorrhage, Richardson, W. L., 592.

Cleft Palate. An improved appliance in the treatment of cleft palate, Baker, W. A., 127, 134.

Climate. Some observations on Southern California and Colorado, Davenport, F. H., 554.

Club-foot. On the use of force in the treatment of resistant club-foot, Bradford, E. H., 265.

Cohen, J. S. A case of complete paralysis of the left vocal band in extreme abduction, the result of an incised wound of the neck, 495.

Collodion. Some surgical uses of collodion, Gaugee, S., 166.

Colon. Downward displacement of the transverse colon; three cases, with autopsies, Thomas, C. H., 1; downward displacement of the transverse colon, Williams, E. T., 45.

Connecticut. Typhoid and malarial fevers in Connecticut, 117; malaria and diphtheria in Connecticut, 384.

Contagious Diseases. A bill to prevent the spread of contagious diseases among cattle, 455.

Coordination. Paths of coördination, Spitzka, E. C., 231.

Cowles, E. A case of hysteroid convulsions, 368.

Cox, J. B. Salivary calculi of the right sub-maxillary gland, 35.

Crandall, C. R. Case in practice; chronic pleuritis with excessive sanguineous effusion, 305.

Cremation. Cremation in China, 140; a New England cremation society, 187.

Cripps, H. Excision of the rectum for cancer, 598.

Crossdale, H. T. Vesico-vaginal fistula with inverted bladder, 516.

Croup. The treatment of membranous croup, 443; tracheotomy in croup and diphtheria, Montgomery, E. E., 567.

Crypta Syphilitica, 430.

Cushing, B. A mother thirteen years of age, 449; St. Mary's Lying-in Hospital, 363.

Cutaneous System. Abnormal elasticity of the skin, Ingalls, W., 61; an improved method in the treatment of certain forms of skin affections, Morrow, P. A., 231; acute eczema in pregnancy, Abbot, S. L., 276; pathological conditions of the skin following the internal use of borax, Wigglesworth, E., 404; report on dermatology, Tilden, G. H., 411.

Cutler, E. G. Protracted lethargy after the use of bromide of sodium by one having the morphia habit, 248, 256.

Cuzzi. Duration of the menstrual hæmorrhage in relation to the development of the fœtus at term, and to multiple pregnancy, 382.

D., S. H. Sea-water for streets; salt on street railways, 69.

Dalton, J. C. The differences in form of the adult head, 229.

Daly, W. H. Gunshot wound of the larynx, involving the vocal bands, 494.

Davenport, F. H. Some observations on Southern California and Colorado, 554.

Davis, H. G. The treatment of hip-joint disease; extension better than excision, 116; some suggestions upon cerebro-spinal meningitis, 262.

Death. Permits and burials in Providence, 19; mortality statistics of Providence, R. I., for the year 1883, 94.

DeBlois, T. A. Congenital web of the vocal bands, with cases, 494; cases of buccal tuberculosis, 513; tonsilitis, 514.

Delavan, D. B. Permanent unilateral paralysis of laryngeal abductors, following cerebral hæmorrhage; unique case, 512; practical suggestions upon the alimentation of patients suffering from dysphagia, 536.

Dentistry. Progress in dentistry, Rollins, W. H., 582, 606.

Derby, H. A case of sudden amaurosis; recovery, 126.

Dermatology. Report on dermatology, Tilden, G. H., 413.

Detention in asylums, Parsons, R. L., 110.

Dietetics. Diagnosis and treatment of syphilis, 205.

Diabetes. The clinical examination of diabetic urine by Duhomme's test, Hurd, E. P., 21; diabetic coma, Edes, R. T., 495.

Digestive System. Downward displacement of the transverse colon; three cases, with autopsies, Thomas, C. H., 1; salivary calculi of the right submaxillary gland, Cox, J. B., 35; liver of chicken with tubercular growths, MacConnell, W. G., 38; downward displacement of the transverse colon, Williams, E. T., 45; hour-glass contraction of stomach, Musser, J. H., 88; the treatment of follicular tonsilitis, Garland, G. M., 103; a case of chronic ulcer of the duodenum, Homans, C. D., 104; detention in asylums, Parsons, R. L., 110; an improved appliance in the physiological treatment of cleft palate, Baker, W. A., 127, 134; colloid cancer of the appendix vermiformis, Draper, F. W., 131; two cases of abdominal section to discover the cause of intestinal obstruction, Homans, J., 145, 156; foreign bodies removed from the œsophagus and the urethra, Gay, G. W., 157; tubercular ulcers of intestines with perforation, Hughes, W. E., 206; actinomycosis of the peritonæum and abdominal organs in man, 259; artificial inflation of the colon with gas, Vickery, H. F., 332; cases of rupture of the liver, Draper, F. W., 333, 349; collection of three gall-stones, Doe, O. W., 348; case of epithelioma of the stomach and colon, presenting singular difficulty of diagnosis, Packard, J. H., 371; malignant disease of the peritonæum and abdominal viscera, Hornet, V., 372; typhilitis and perityphilitis, Wheeler, L., 409; history of a case of perihepatic abscess, Bruen, E. T., 412; four cases of strangulated hernia, 416; pseudo-membranous enteritis, Doe, O. W., 441; excision of a portion of intestine, including part of the ileo-cæcal valve, for the cure of fæcal fistula in right groin, Porter, C. B., 457, 467; stricture of the œsophagus, Lincoln, R. P., 512; tonsilitis, DeBlois, T. A., 514; treatment of ulcer of the stomach, 521; practical suggestions upon the alimentation of patients suffering from dysphagia, Delavan, D. B., 536; progress in dentistry, Rollins, W. H., 582, 606; excision of the rectum for cancer, Cripps, H., 598.

Diphtheria. Sudden death in diphtheria, Longaker, D., 422; diphtheria with complications, Hayward, G. G., 515; tracheotomy in croup and diphtheria, Montgomery, E. E., 567.

Distoma. The life-history of the distoma hepaticum, Minot, C. S., 418.

Doe, O. W. Collection of three gall-stones, 348; retained placenta, 436, 441; pseudo-membranous enteritis, 441; removal of fœtal bones by rectum, 441.

Draper, F. W. Recent progress in forensic medicine, 80; colloid cancer of the appendix vermiformis, 131; cases of rupture of the liver, 339, 349.

Drugs. State prosecutions for adulterated drugs, 95; modern legislation relative to adulteration of food and drugs, Abbott, S. W., 241, 253; "further legislation to prevent the adulteration of food and drugs," 378.

Drunkard and the doctor, 281.

Ductless Glands, diseases of. Addison's disease, Howe, O. T., 181.

Dulles, C. W. Enormous hypertrophy of the heart, 16.

Dwight, T. Recent progress in anatomy, 225; lectures in the course on topographical anatomy, 505; modern methods in anatomy, 585.

Dysphagia. Practical suggestions upon the alimentation of patients suffering from dysphagia, Delavan, D. B., 536.

Ear. Recent progress in otology, Green, J. Orne, 3; treatment of diseases of the ear, Morse, H. L., 164; inflammation of both tympana and both labyrinths in scarlet fever, Green, J. Orne, 228; round-celled sarcoma of the meatus auditorius, Green, J. Orne, 348; serous effusions in the tympanum, Green, J. Orne, 553, 569; specimen illustrating progressive movement of dermoid lining of external auditory canal, Hooper, F. H., 560.

Early Rising. The therapeutics of early rising, 473.

Eczema. Acute eczema in pregnancy, Abbot, S. L., 276.

Edes, R. T. Clinical lecture on a case of myxœdema, 385; diabetic coma, 495; unusual cases of scurvy, 607; materia medica at the Harvard Medical School, 620.

Edinburgh. Edinburgh tercentenary, 379; the medical magnates of Edinburgh, 401; extramural teaching in Edinburgh, 402; some old Edinburgh surgeons, 499; report of cases treated in Edinburgh Infirmary, 619.

Editorials. Annus medicus incipiens, 18; literature in medicine, 18; permissive euthanasia, 19; the decision in regard to the prize for essays on malignant disease, its cure, and the methods of investigation to be followed, 20; nerve-stretching, 40; the National Board of Health, the report for the year 1882-1883, 41; the Massachusetts Board of Health, 41; the prize offer by the Worshipful Company of Grocers, London, 42; State prosecutions for adulterated drugs, 95; annual reports of the president and treasurer of Harvard University, 1882-1883, 95; Quarantine and Health, Charity, and Lunacy in the city and State of New York, 96; the beating of dogs, 89; is there a non-contagious erysipelas? 90; some out-time doctors, 113; emotional insanity, and the defense of Nutt for killing his father's murderer, 113; the preservation of the Adirondacks, 114; the simulation of stone, 138; Boston's improved sewerage system, 139; cremation in China, 140; transitory aphasia in typhoid fever, 161; another United States Pharmacopœia; is it needed? 161; medical attendance upon sick paupers, 162; "trance" as a symptom of hysteria, 185; endowment of medical schools; bequest of the late Dr. Calvin Ellis to the Harvard School, 186; a New England cremation society, 187; restraint at the Utica Insane Asylum, 187; the metric system and the Pyramid of Ghizeh, 210; the determination of sex at will, 211; the relation of laboratories to medical science and medical education, 233; periodical change of color of the hair, 234; new national pharmacopœia, 235; reports on cholera from Surgeon-General Hunter and Dr. Robert Koch, 258; actinomycosis of the peritonæum and abdominal organs in man, 259; the reflex effect of dealing in "futures," 259; the drunkard and the doctor, 281; shall the United States Pharmacopœia be the legal standard for drugs in Massachusetts, or shall it be some one of the commentaries or dispensatories, 282; the hygiene of study, 305; Dr. Thomas Trotter, surgeon to the fleet, 306; the sanitary condition of the school-houses of the city of Lynn, 329; the foot and mouth disease, 333; insanity and the law, 354; modern and ancient leprosy in Syria, 354; legislation in New York for the protection of food products, 356; "further legislation to prevent the adulteration of food and drugs," 378; the Edinburgh tercentenary, 379; reform of medical service on ships, 401; the medical magnates of Edinburgh, 401; extra-mural teaching in Edinburgh, 402; the meetings of the American medical and other associations at Washington, 425; the doctrine of evolution as applied to pathological states of the nervous system, 425; the subcutaneous use of morphine in elderly persons, 427; Dr. Willard Parker, 427; the Cæsarean section as performed by savages, 450; etherization by the rectum, 451; the New York State Asylum for Insane Criminals, 452; the meeting of the American Medical Association at Washington, 473; the therapeutics of early rising, 473; leprosy in the Hawaiian Islands, 474; the diagnostic value of the discovery of the "bacillus tuberculosis" in sputum, 498; some old Edinburgh surgeons, 499; testamentary capacity, 500; treatment of ulcer of the stomach, 521; the cemeteries and water-supply of Panama, 522; the "taxation" theory of expert testimony, 546; a word for military drill in schools, 547; a verdict of manslaughter against an irregular practitioner, 547; the Eighth International Medical Congress, 569; a new line of research for cerebral physiologists, 569; the one hundred and third annual meeting of the Massachusetts Medical Society, 569; The Massachusetts Medical Society and women, 594; the importance of a knowledge of the physical characters of drugs, 595; the tubercle bacillus, 618; report of cases treated in Ward XIX., Royal Infirmary, Edinburgh, 619.

Education. Annual reports of the president and treasurer of Harvard University, 1882-1883, 95; endowment of medical schools; bequest of the late Dr. Calvin Ellis to the Harvard School, 186; the American Practitioner on the Louisville Medical College, 238; the Ohio State Medical Society and medical education, 310; extramural teaching in Edinburgh, 402; military drill in schools, 547; materia medica at the Harvard Medical School, Edes, R. T., 620.

Edwards, W. A. Carcinoma of the uterus; fatty kidneys and empyema, 88.

Elephant. The sacred white elephant, 190.

Elliot, G. Enteric fever in New Haven, 361.
Elliot, J. W. The treatment of retroversion of the uterus with adhesions, 193, 398.
Elsberg, L. Spasms of the glottis, 513.
Embryos. Renewed request for embryological material, Minot, C. S., 189.
Endometritis. Some considerations on endometritis, Jacobi, M. P., 468.
Enteric Fever. Transitory aphasia in typhoid fever, 162; ætiology of typhoid fever, Janeway, E. G., 203; the treatment of typhoid fever, 300; enteric fever in New Haven, Elliot, G., 361; an epidemic of typhoid fever at a summer hotel, Woodward, L. F., 364.
Enteritis. Pseudo-membranous enteritis, Doe, O. W., 441.
Ernst, H. C. Hartzell's method for staining the tubercle bacillus, 213.
Erysipelas. Is there a non-contagious erysipelas? 90.
Ether administered by the rectum, 405; etherization by the rectum, Post, A., 442, 451.
Ethics. The value of ethical codes for practitioners of medicine, Stillé, A., 404.
Euthanasia, permisive, 19.
Evolution. The doctrine of evolution as applied to pathological states of the nervous system, 425.
Experts. The "taxation" theory of expert testimony, 546, 573.
Eye. A case of sudden amaurosis, recovery, Derby, H., 126; intraocular changes in cases of cerebral tumor, Williams, C. H., 257; blepharospasm, Miller, H. G., 304; loss of sight from injury of facial nerve, O'Leary, C., 304; case of foreign body in the orbit, Williams, C. H., 348; three cases of homonymous hemianopia, Wadsworth, O. F., 483, 495; recent progress in ophthalmology, Wadsworth, O. F., 596; temporary blindness following labor, Schiedt, P. M., 569.

Fabre. Hysterical pseudo-phthisis, 70.
Farlow, J. W. An antiseptic absorbent pad, 544.
Feeble-minded Children. Institution in Pennsylvania, 574.

Fibroids. The medical treatment of uterine fibroids, Blake, J. G., 564.
Field, H. M. Retained placenta of abortion, 524; six generic drug modifications, 601.
Fifield, W. C. B. Suppression of urine treated with cantharides, 271; high temperatures after labor without obvious cause, 275; spontaneous phlebitis, 301; external urethrotomy, Wheelhouse's operation, 338.
Finger-contraction, Dupuytren's, Abbe, R., 419.
Fisher, H. M. Case of phthisis with empyema, 86.
Fitz, R. H. Amputation in senile gangrene, 349; senile gangrene, 544.
Flint, A. Pathological and practical relations of the bacillus tuberculosis, 108; scarlet fever, 539.
Fœtus, malformed, Green, C. M., 61.
Folsom, C. F. Two cases of injury to the back, 97, 104.
Food. Modern legislation relative to adulteration of food and drugs, Abbott, S. W., 241, 253; on milk supplies in large cities, Morris, J. C., 315, 323, 349; the milk supply of Boston, and the benefit to be derived from spaying cows, Abbott, S. W. F., 317, 332; legislation in New York for the protection of food products, 356; "further legislation to prevent the adulteration of food and drugs," 378.
Foot-Ball. The killed and wounded, 358; accidents, 526.
Foot and Mouth Disease, 330.
Forensic Medicine. Recent progress in forensic medicine, Draper, F. W., 89.
Fowler, G. B. The detection of albumen in urine, 299.
Fractures. The effects of adduction and abduction on the length of the limb in fractures of the neck of the femur, Halsted, W. S., 231.
Francis, G. E. A new antiseptic dressing, 429.

Gamgee, S. Some surgical uses of collodion, 166.
Gangrene. Senile gangrene, Fitz, R. H., 349, 544.
Gannett, W. W. Diagnosis and pathology of dermoid cysts, 62.
Garland, G. M. The treatment of follicular tonsilitis, 103; the treatment of gleet an l gonorrhœal strictures by Otis's method, 181.
Garrigues, H. J. Prevention of puerperal infection, 14; the removal of the after-birth, 373.
Gay, G. W. A fatal case of internal urethrotomy, 2, 6; foreign bodies removed from the œsophagus and the urethra, 157; a year's experience in tracheotomy, 320; the plaster posterior splint in the treatment of fractures of the leg, 585.
General Diseases. Syphilis of the brain and membranes, Wood, H. C., 25; a case of cerebro-spinal syphilis, Post, A., 28; section of large spindle-celled sarcoma, MacConnell, W. G., 38; liver of chicken with tubercular growths, MacConnell, W. G., 38; case of mammary cancer; operation; subsequent catarrhal pneumonia, with cancer of the lungs; autopsy, Green, C. M., 59; neplrectomy for the removal of cancerous or sarcomatous tumors of the kidney, Homans, J., 73; is there a non-contagious erysipelas? 90; pathological and practical relations of the bacillus tuberculosis, Flint, A., 108; typhoid and malarial fevers in Connecticut, 117; colloid cancer of the appendix vermiformis, Draper, F. W., 131; clinical aspects of cerebral syphilis, Wood, H. C., 196, 220; ætiology of typhoid fever, Janeway, E. G., 203; specimens of sarcoma, etc, Peabody, G. L., 205; diagnosis and treatment of syphilis, Detmold, 205; anuria from compression of the ureters by cancerous disease, Minot, F., 227; topical cardiac blistering in the treatment of acute rheumatism, Parks, N. O'D., 303; malignant disease of the bladder, Burge, W. J., 304; locomotor ataxia and syphilis, Weber, L., 325; enteric fever in New Haven, Elliot, G., 331; an epidemic of typhoid fever at a summer hotel, Woodward, L. F., 364; malaria and diphtheria in Connecticut, 382; sudden death in diphtheria, Longaker, D., 442; scarlet fever in the fœtus in utero and in the mother at the ninth month of pregnancy, Leale, C. A., 445; a contribution to the study of congenital syphilis, Mackenzie, J. N., 492; diabetic coma, Edes, R. T., 495; diphtheria with complications, Hayward, G. G., 515; the contagiousness of typhoid, Cabaniss, T. T., 524; chancre of the tonsils, Taylor, R. W., 537; scarlet fever, Flint, A., 539; colloid carcinoma, Hearn, J., 565; a case of Paget's Disease, Hearn, J., 565; sarcoma of testicle, Schweinitz, G. de, 566; tracheotomy in croup and diphtheria, Montgomery, E. E., 567; unusual cases of scurvy, Edes, R. T., 607.
Generative System. Two cases of uterine polypus, Minot, F., 58, 62; dermoid cyst of the right ovary, Blake, J. G., 62; diagnosis and pathology of dermoid cysts, Gannett, W. W., 62; carcinoma of the uterus; fatty kidneys and empyema, Edwards, W. A., 88; parovarian cysts, Goodell, 118; malformation of the vagina simulating extrophy of the bladder, 132; letter from London, Manton, W. P., 141; fatal result from injection of the tunica vaginalis with iodine, Wyeth, J. A., 144; a substitute for strapping the testicle and the treatment of hydrocele, Warren, J. C., 157; the treatment of gleet and gonorrhœal strictures by Otis's method, Garland, G. M., 181; the treatment of retroversion of the uterus with adhesions, Elliot, J. W., 193, 398; cancer of uterus, Hughes, W. E., 207; the operation of ovariotomy, Homans, J., 337; reasons for the early removal of ovarian tumors, Irish, J. C., 344; tumor of the uterus, Burrell, H. L., 348; malignant disease of the testicle tapped for hydrocele, Roberts, J. B., 374; sea voyage and amenorrhœa, Chadwick, J. R., 448; some considerations on endometritis, Jacobi, M. P., 468; vesico-vaginal fistula, with inverted bladder, Crosadale, H. T., 516; hysteria, as affected by removal of the ovaries, Walton, G. L., 529, 542; the medical treatment of uterine fibroids, Blake, J. G., 564; sarcoma of testicle, Schweinitz, G. de, 566.
Ghizeh. The metric system and the Pyramid of Ghizeh, 210.
Gibb, J. S. Umbilical hæmorrhage, 422.
Gleet. The treatment of gleet and gonorrhœal strictures by Otis's method, Garland, G. M., 181.
Goodell (Philadelphia). Parovarian cysts, 118.
Graham, D. Brittle bones, 467.
Green, C. M. Report on obstetrics, 33; case of mammary cancer; operation; subsequent catarrhal pneumonia, with cancer of the lungs; autopsy, 59; malformed fœtus, 61; the delivery of the second fœtus in labor with twins, 62; report of a summer course in obstetrics, 389, 398; podalic version, and abdominal pressure upon the after-coming head, 449.
Green, J. Orne. Recent progress in otology, 3; inflammation of both tympana and both labyrinths in scarlet fever, 228; round-celled sarcoma of the meatus auditorius, 318; serous effusions in the tympanum, 553, 560.
Griffin, A. C. A case of pustula maligna, 429.
Griswold, G. Notes on albuminaria, 538.

Hæmophilia. Case of umbilical hæmorrhage, Richardson, W. L., 592.
Hæmoptysis in the course of puerperal septicæmia, Hosmer, A., 276.
Hair. Periodical change of color of the hair, 234.
Halsted, W. S. Refusion in carbonic oxide poisoning, 22; the effects of adduction and abduction on the length of the limb in fractures of the neck of the femur, 231.
Hartzell. A new method for the detection of the bacillus tuberculosis, 166.
Hartzell's method for staining the tubercle bacillus, Ernst, H. C., 213.
Harvard University. Annual Report of the President and Treasurer of Harvard University, 1882-1885, 65; the bequest of the late Dr. Calvin Ellis, 70, the late Dr. Calvin Ellis, 166; endowment of medical schools; bequest of the late Dr. Calvin Ellis to the Harvard School, 186.
Haven, H. C. Cephalhæmatoma, 184.
Hayward, G. G. Diphtheria with complications, 515.
Hearn, J. A case of Paget's Disease, 565; colloid carcinoma, 565.
Heart. Probable transuxion of the heart with recovery, 406.
Heating. The heating of domiciles, 89.
Hernia. Four cases of strangulated hernia, Homans, J., 416.
Hills, W. B. Report on medical chemistry, 130.
Hinsdale, G. Fracture of the base of the skull, 85; necrosis of the temporal bone and brain abscess, 85.
Hip-joint. A successful case of amputation at the hip-joint, Bradford, E. H., 257; extension better than excision, Davis, H. G., 116.
Holmes, O. W. New facts about Dr. O. W. Holmes, 344.
Homans, C. D. A case of chronic ulcer of the duodenum, 104.
Homans, J. The operation of ovariotomy, 337; two cases of abdominal section to discover the cause of intestinal obstruction, 145; nephrectomy for the removal of cancerous or sarcomatous tumors of the kidney, 73, 156; four cases of strangulated hernia, 416.
Hooper, F. H. A rare form of tumor (cavernous papilloma) of the vocal cord, 514; specimen illustrating progressive movement of dermoid lining of external auditory canal, 569.
Hopkins, Mrs. Of Hartford upon Connecticut, 598
Hornet, V. Malignant disease of the peritoneum and abdominal viscera, 372.
Hosmer, A. Hæmoptysis in the course of puerperal septicæmia, 276.
Hospital. Hospital absenteeism, 14; The Children's Hospital, Boston, 46.
Howe, O. T. Addison's disease, 181.
Hughes, W. E. General tuberculosis of serous membranes, 206; tubercular ulcers of intestines with perforation, 206; phthisis following empyema; amyloid kidneys; cancer of uterus, 207; secondary tuberculosis of the bladder, ureter, kidney, and suprarenal body, 207.
Hurd, E. P. The clinical examination of diabetic urine by Duhomme's test, 21; cerebral localizations, 561.

Macewen (Glasgow). A contribution to the surgery of the brain, 333.
Mackenzie, J. N. A contribution to the study of congenital syphilis, 492.
Malaria and diphtheria in Connecticut, 382.
Malignant Pustule. Pustula maligna, Griffin, A. C., 429; malignant pustule, Janney, W. S., 423.
Manslaughter. A verdict of manslaughter against an irregular practitioner, 547.
Manton, W. P. Letter from London, 141.
Mason, A. L. Cerebro-spinal meningitis; five cases; one, of the fulminant (foudroyant) type, treated by subcutaneous injection of apomorphia, morphine, and atropine; recovery; one autopsy, 121, 132.
Massachusetts Board of Health, 41.
Materia Medica and Therapeutics. Nitro-glycerine and the chloride of gold and sodium in the treatment of albuminuria, Bartholow, R., 92; antiseptics in the New York Hospital, 106; the use of the menthol cone as an anodyne, Wendt, E. C., 109; some surgical uses of collodion, Gamgee, S., 166; a bill to prepare and publish a national pharmacopœia for the United States, 168; Report on Materia Medica, Bolles, W. P., 200; suppression of urine treated with cantharides, Fifield, W. C. B., 271; criticisms, from a chemical point of view, on some favorite prescriptions, Leffmann, H., 411; the subcutaneous use of morphine in elderly persons, 427; the therapeutics of early rising, 473; the importance of a knowledge of the physical characters of drugs, 595; the principles of modern therapeusis, Wood, H. C., 597; six generic drug modifications, Field, H. M., 601; materia medica at the Harvard Medical School, Edes, R. T., 620.
Mathieson (Ontario). A case of extra-uterine gestation. Delivery of a living child per vaginam. Removal of placenta. Recovery, 622.
Medical Examiners. Rhode Island Medical Society, 36.
Melancholia. Cases of melancholia, Tuttle, G. T., 77, 84.
Menthol. The use of the menthol cone as an anodyne, Wendt, E. C., 109.
Metric System and the Pyramid of Ghizeh, 210; a plea for consistency, 238.
Military Drill in schools, 547.
Milk. On milk supply in large cities, Morris, J. C., 315, 323; the milk supply of Boston and the benefit to be derived from spaying cows, Abbott, L. F., 317, 349.
Miller, H. G. Blepharospasm, 304.
Mind. Cases of melancholia, Tuttle, G. T., 77, 84; emotional insanity, and the defense of Nutt for killing his father's murderer, 113; hallucinations from salicine, 118; restraint at the Utica Insane Asylum, 187; general paralysis of the insane, Jelly, G. E., 217, 227, 246; recent progress in the construction of insane hospitals and management of the insane, Channing, W., 295, 321; insanity and the law, 354; the New York Asylum for Insane Criminals, 452; effects of political events on the forms of insanity, Saulle, L. du, 574; institution for feeble-minded children in Pennsylvania, 574.
Minot, C. S. Renewed request for embryological material, 189; the life-history of the distoma hepaticum, 418.
Minot, F. Two cases of uterine polypus, 58, 62; on the treatment of acute pneumonia, 169, 183; anuria from compression of the ureters by cancerous disease, 227; case resembling infantile paralysis caused by improper diet, 275.
Mitchell, S. W. Note from Dr. Weir Mitchell, 21; vivisection, 533.
Monsters. Malformed fœtus, Green, C. M., 61; a case of plagiomicrocephalia, Lukin, M., 117; malformation of the vagina, simulating extrophy of the bladder, Rotch, T. M., 132; an acephalous monster, Brown, D., 539.
Montgomery, E. E. Tracheotomy in croup and diphtheria, 567.
Morphine. The subcutaneous injection of morphine in elderly persons, 427.
Morris, J. C. On milk supply in large cities, 315.
Morrow, P. A. An improved method in the treatment of certain forms of skin affections, 231.
Morse, H. L. Treatment of diseases of the ear, 164.
Musser, J. H. Atheroma, dilatation, and aneurism of the aorta, etc., 87; hour-glass contraction of the stomach, 88; lung from a case of pleuro-pneumonia, complicated with delirium tremens, 88.
Myxœdema. Clinical lecture, Edes, R. T., 385.

Nancrede, C. B. Three cases illustrating some points in the pathology of certain injuries of the shoulder-joint, 387.
National Board of Health. Report for the year 1882–1883, 41.
Nervous System. Neurotic affections accompanying joint lesions, Jacoby, G. W., 10; syphilis of the brain and membranes, Wood, H. C., 25; a case of cerebro-spinal syphilis, Post, A., 28; nerve stretching, 40; cases of lesion of the brain with unilateral symptoms, Webber, S. G., 49, 60; what is meant by nervous prostration? Bartholow, R., 58, 63; hysterical pseudo-phthisis, Fabre, 70; necrosis of the temporal bone and brain abscess, Hinsdale, G., 85; two cases of injury to the back, Folsom, C. F., 97, 104; cerebro-spinal meningitis, five cases, Mason, A. L., 121, 132; the simulation of stone, 133; transitory aphasia in typhoid fever, 161; "trance" as a symptom of hysteria, 185; clinical aspects of cerebral syphilis, Wood, H. C., 196, 220; general paralysis of the insane, Jelly, G. E., 217, 228, 246; paralysis of coordination, Spitzka, E. C., 233; the reflex effect of dealing in "futures," 250; some suggestions upon cerebro-spinal meningitis, Davis, H. G., 262; a case of "wasting palsy" (partial), Read, G. M., 268; case resembling infantile paralysis caused by improper food, Minot, F., 275; insular sclerosis of the posterior columns of the spinal cord, Pepper, W., 313; locomotor ataxia and syphilis, Weber, L., 325; a contribution to the surgery of the brain, Macewen, 333; a case of hystero-id convulsions, Cowles, E., 368; the doctrine of evolution as applied to pathological states of the nervous system, 425; multiple neuritis, Webber, S. G., 441; spinal irritation and neurasthenia, Liebmann, G., 460, 470; cerebral localizations, Hurd, E. P., 561; a new line of research for cerebral physiologists, 569.
Neuritis. Multiple neuritis, Webber, S. G., 441.
New Haven. Enteric fever in New Haven, Eliot, G., 361.
Newport. The winter climate of Newport, 168.
New York. Quarantine and Health, Charity, and Lunacy in the city and State of New York, 66; antiseptics in the New York Hospital, 106
Nichols, A. Fatal wait on street railways; its medico-legal aspects, 92.
Nitric Acid. Poisoning by fumes of nitric acid, Temple, W. W., 496.
Nutt. Emotional insanity and the defense of Nutt for killing his father's murderer, 113.

Obstetrics. Report of a summer course in obstetrics, Green, C. M., 389, 398.
Ohio State Medical Society and medical education, 310.
Old-time Doctors', 113.
O'Leary, C. Aneurism of the thoracic aorta, 37; loss of sight from injury of facial nerve, 304.
Opium Habit. Protracted lethargy after the use of bromide of sodium by one having the morphia habit, Cutler, E. G., 248, 256.
Orthopraxy. A new hip splint, Cabot, A. T., 6; excision in hip disease; are its prognosis and its results better than those of a spontaneous cure, Bradford, E. H., 7; the treatment of hip-joint disease, extension better than excision, Davis, H. G., 116; the orthopædic surgeon as a mechanical engineer, Shaffer, N. M., 189; on the use of force in the treatment of resistant club-foot, Bradford, E. H., 265; report on orthopædic surgery, Bradford, E. H., 394; Dupuytren's finger-contraction, Abbe, R., 419.
Osteo-Myelitis of tibia, Wilson, C. M., 136.
Otis, E. O. The use of tobacco by boys, 89, 101; a case of cysto-pyelitis, or pyelo-cystitis coincident with pyelitis, 290, 297.
Ovariotomy. The operation of ovariotomy, Hamans, J., 337; reasons for the early removal of ovarian tumors, Irish, J. C., 314; hysteria, as affected by removal of the ovaries, Walton, G. L., 529, 542.

Packard, J. H. Case of epithelioma of the stomach and colon, presenting some difficulty of diagnosis, 371.
Paget's Disease, case of, Hearn, J., 565.
Panama. The cemeteries and water supply of Panama, 522.
Paracentesis of the pericardium, Macdonald, J. W., 22.
Parks, N. O'D. Topical cardiac blistering in the treatment of acute rheumatism, 393.
Paupers. R. L. Detention in asylums, 110.
Passengers. Carriage of passengers by sea, 406.
Pathology. Recent progress in pathology and pathological anatomy, Whitney, W. F., 438, 462, 487.
Peabody, G. L. Specimens of sarcoma, etc., 205; the treatment of typhoid fever, 300.
Pepper, W. Insular sclerosis of the posterior columns of the spinal cord, 313.
Petersen, O. Pressure in the treatment of buboes, 5.
Pharmacopœia. Another United States pharmacopœia; is it needed? 161; a bill to prepare and publish a national pharmacopœia for the United States, 168; the government control of the United States Pharmacopœia, 213; new national pharmacopœia, 235; shall the United States Pharmacopœia be the legal standard for drugs in Massachusetts, or shall it be some one of several commentaries or dispensatories? 282; relative cost, as legal standards, of United States Pharmacopœia and Dispensatory, 334.
Phlebitis. Spontaneous phlebitis, Fifield, W. C. B., 397.
Phthisis. Hysterical pseudo-phthisis, Fabre, 70; case of phthisis, with empyema, Fisher, H. M., 86; laryngeal complications of pulmonary phthisis, Knight, F. I., 540; phthisis following empyema; amyloid kidneys; cancer of uterus, Hughes, W. E., 207.
Physiology. The determination of sex at will, 211; the grant of £10,000 to the physiological Laboratory of Oxford considered as a "national disaster," 214; periodical change of color of the hair, 234; a new line of research for cerebral physiologists, 569; methods of instruction and research in physiology, Bowditch, H. P., 584.
Pilo-Nidal Sinus, Porter, C. B., 398.
Pinnock (Victoria). Scarlatina coexistent with typhoid fever, 526.
Placenta. Retained placenta, Doe, O. W., 436, 441; bi-polar version in placenta prævia, 622.
Plaster Supports, Browne, W. T., 289; the plaster posterior splint in the treatment of fracture of the leg, Gay, G. W., 585.
Pleurisy. Case of chronic pleuritis with excessive sanguinolent effusion, Crandall, C. R., 580.
Pneumonia. On the treatment of acute pneumonia, Minot, F., 169, 183

"infectious" pneumonia; gangrene of lung; fetid empyema; recovery, Broughton, H. W., 172.

Poisons. Refusion in carbonic-oxide poisoning, Halsted, W. S., 22; protracted lethargy after the use of bromide of sodium by one having the morphia habit, Cutler, E. G., 248; poisonous wall-papers, 262; poisoning by fumes of nitric acid, Temple, W. W, 496; inhalation of ammonia, Swan, C. W., 497.

Polaillon. Hydatid cyst of the abdominal walls, 310.

Politics. Effects of political events on the forms of insanity, Saulle, L. du, 574.

Polypus. Two cases of uterine polypus, Minot, F., 58, 62.

Porter, C. B. A case of plio-nidal sinus, 398; diphtheritic perineal wound; chronic cystitis; bilateral incision of prostate for removal of stone; acute suppurative peritonitis; autopsy, 399; removal of a fragment of catheter from the bladder, 399; excision of a portion of intestine, including a part of the ileo-cæcal valve, for the cure of fæcal fistula in right groin, 457, 467.

Post, A. A case of cerebro-spinal syphilis, 28; etherization by the rectum, 442.

Pregnancy, Affections Connected With. Prevention of puerperal infection, Garrigues, H. J., 14; an unusual obstetrical case, Strong, C. P., 39, 36; report on obstetrics, Green, C. M., 33; a case of tubal pregnancy, Terry, H., 37; the delivery of the second fœtus in labor with twins, Green, C. M., 62; pregnancy and morphinism, Féré, 117; the treatment of retained secundines after abortion, Braunan, J. W., 147; the prevention and treatment of puerperal fever (Discussion), Thomas, T. G., 178; high temperatures after labor without obvious cause, Fifield, W. C. B., 275; the induction of labor, Richardson, W. L., 276; hæmoptysis in the course of puerperal septicæmia, Hosmer, A., 276; method of management of face presentation, Richardson, W. L., 276; acute eczema in pregnancy, Abbot, S. L., 276; prolapse of the anterior wall of the vagina during labor, Lyman, G. H., 276; a case of face presentation with some remarks on the treatment of this class of cases, Swift, J. B., 293, 298; the treatment of puerperal fever, Terry, H., 303; the removal of the after-birth, Garrigues, H. J., 373; duration of the menstrual hæmorrhage in relation to the development of the fœtus at term, and to multiple pregnancy, Cuzzi, 382; report of a summer course in obstetrics, Green, C. M., 389, 398; retained placenta, Doe, O. W., 436, 441; removal of fœtal bones by rectum, Doe, O. W., 441; podalic version, and abdominal pressure upon the after-coming head, Green, C. M., 449; the Cæsarean section as performed by savages, 450; retained pieces of abortion, Field, H. M., 524; abdominal section for extra-uterine pregnancy, Macdonald, A., 525; an acephalous monster, Brown, D., 539; puerperal convulsions, Blake, J. G, 565; puerperal case with numerous complications, Willets, M., 566; clinical phenomena following the puerperal state in two cases, Schiedt, P. M., 566; temporary blindness following labor, Schiedt, P. M., 566; retained pieces of abortion, with hæmorrhage, Brown, M. L., 573; a case of extra-uterine gestation; delivery of a living child per vaginam; removal of placenta, recovery, Mathieson, 622; bi-polar version in placenta prævia, 622.

Prizes. The decision in regard to the prize for essays on malignant diseases, 20; the prize offer by the Worshipful Company of Grocers, London, 42, 48.

Prosecutors. Public prosecutors and private persecutors, 94.

Providence. Mortality statistics of Providence, R. I., for the year 1883, 94.

Puerperal Convulsions, Blake, J. G., 565.

Puerperal Fever. The prevention and treatment of puerperal fever, Thomas, T. G., 178; the treatment of puerperal fever, Terry, H., 303.

Puerperal Infection, prevention of, Garrigues, H. J., 14.

Pustula Maligna, Griffin, A. C., 429; malignant pustule, Janney, W. S., 433.

Rags. Importation of rags from Egypt, 478.

Read, G. M. A case of "wasting palsy" (partial), 268.

Recent Progress. Otology, Green, J. Orne, 3; obstetrics, Green, C. M., 33; forensic medicine, Draper, F. W., 80; medical chemistry, Hills, W. B., 130; anatomy, Dwight, T., 225; theory and practice of medicine, Shattuck, G. B., 249, 270; construction of insane hospitals and management of the insane, Channing, W., 295, 321; diseases of children, Rotch, T. M., 365; dermatology, Tilden, G. H., 413; pathology and pathological anatomy, Whitney, W. F., 438, 462, 487; ophthalmology, Wadsworth, O. F., 556; dentistry, Rollins, W. H., 582, 606.

Rectum. Excision of the rectum for cancer, Cripps, H., 598.

Renal Abscess, Stedman, C. E., 591.

Respiratory System. Case of mammary cancer, operation, subsequent catarrhal pneumonia, with cancer of the lungs; autopsy, Green, C. M., 59; hysterical pseudo-phthisis, Fabre, 70; case of phthisis with empyema, Fisher, H. M., 86; lung from a case of pleuro-pneumonia, complicated with delirium tremens, Musser, J. H., 88; lobar pneumonia in a child, Rotch, T. M., 132; chronic nasal catarrh; removal of hypertrophied tissue, 132; on the treatment of acute pneumonia, Minot, F., 169, 183; "infectious" pneumonia; gangrene of lung; fetid empyema; recovery, Broughton, H. W., 172; recent progress in the treatment of thoracic diseases, Shattuck, F. C., 174; hæmoptysis in the course of puerperal septicæmia, Hosmer, A., 276; a year's experience in tracheotomy, Gay, G. W., 320; the treatment of membranous croup, Jacobi, A., 443; the clinical significance of fibrinous exudation upon the mucous membrane of the upper air passages, Bosworth, F. H., 491; a contribution to the study of congenital syphilis (throat), Mackenzie, J. N., 492; retro-pharyngeal abscess, Roe, J. O., 493; congenital web of the vocal bands, with cases, DeBlois, T. A., 494; gunshot wound of the larynx, involving the vocal bands, Daly, W. H., 494; a case of complete paralysis of the left vocal band in extreme abduction, the result of an incised wound of the neck, Cohen, J. S., 495; a rare form of tumor (cavernous papilloma) of the vocal band, Hooper, F. H., 511; a case of ecchondrosis of the laryux, Asch, M. J., 511; a new method for the removal of laryngeal growths, Jarvis, W. C., 511; permanent unilateral paralysis of laryngeal abductors, following cerebral hæmorrhage, unique case, Delavan, D. B., 512; tracheal stenosis, Ingals, E. F., 512; cases of buccal stenosis, DeBlois, T. A., 513; hay fever and its successful treatment, Sajons, C. E., 513; the comparative value of the galvano-cautery in diseases of the nasal and pharyngeal cavities, Shurley, E. L., 513; a contribution to the study of adenoid vegetations at the vault of the pharynx, Robinson, B., 513; spasm of the glottis, Elsberg, L., 513; laryngeal complications of pulmonary phthisis, Knight, F. I., 540; case of chronic pleuritis with excessive sanguinolent effusion, Crandall, C. R., 580; the course of the fever in acute croupous pneumonia, Silvestrini, 622.

Retroversion. The treatment of retroversion of the uterus with adhesions, Elliot, J. W., 398.

Reynolds, J. P., An over-dose of chloral, 151.

Rheumatism. Topical cardiac blistering in the treatment of acute rheumatism, Parks, N. O'D., 303.

Richardson, W. L. The induction of labor, 276; method of management of face-presentation, 276; umbilical hæmorrhage, 592.

Roberts, J. B. The surgical abuse of sponges and of silver wire, 336; malignant disease of the testicle tapped for hydrocele, 372.

Robinson, B. A contribution to the study of adenoid vegetations at the vault of the pharynx, 513.

Robinson, G. D. Governor Robinson's inaugural, 45.

Roe, J. O. Retro-pharyngeal abscess, 493.

Rollins, W. H. Progress in dentistry, 582, 606.

Rotch, T. M. Recent progress in diseases of children, 365; malformation of the vagina, simulating extrophy of the bladder; lobar pneumonia in a young child, 132.

St. Mary's Lying-in Hospital, Cushing, B., 363.

Sajons, C. E. Hay fever and its successful treatment, 513.

Saltcine. Hallucinations from salicine, 118.

Salmon, D. E. The discovery of the germ of swine plague, 285.

Salt. Sea-water for streets, salt on street railways, Nescieus, 44; "sea-water" (?) and salt in the streets, Querens, 69; sea-water for streets, salt on street railways, S. H. D., 69; salt on street railways; its medico-legal aspects, Nichols, A. H., 92; salted tracks, Nescieus, 94.

Saulle, L. du. Effects of political events on the forms of insanity, 574.

Scarlatina coexistent with typhoid fever, Pinnock (Victoria), 526.

Scarlet Fever in the fœtus in utero and in the mother at the ninth month of pregnancy, Leale, C. A., 445; scarlet fever, Flint, A., 539.

Schiedt, P. M. Clinical phenomena following the puerperal state in two cases, 566; temporary blindness following labor, 566.

Schweinitz, G. de. Sarcoma of testicle, 566.

Scurvy. Unusual cases of scurvy, Edes, R. T., 607.

Sea. Carriage of passengers by sea, 406.

Sea-Water for streets, salt on street railways, 44; "sea-water" (?) and salt in the streets, 69; sea-water for streets, salt on street railways, S. H. D., 69.

Serous Membranes. General tuberculosis of serous membranes, Hughes, W. E., 206.

Sewage systems and the preparation of sewage by irrigation and agriculture, Barnes, H. J., 5-7, 603, 609.

Sewerage. Boston's improved sewerage system, 139.

Sex. The determination of sex at will, 211.

Shaffer, N. M. The orthopædic surgeon as a mechanical engineer, 189.

Shattuck, F. C. Recent progress in the treatment of thoracic disease, 174.

Shattuck, G. B. Report on theory and practice of medicine, 249, 270.

Ships. Reform of medical service on ships, 401.

Shoulder-joint. Three cases illustrating some points in the pathology of certain injuries of the shoulder-joint, Nancrede, C. B., 387.

Shurley, E. L. The comparative value of the galvano-cautery in diseases of the nasal and pharyngeal cavities, 513.

Skeleton. Another prehistoric human skeleton, 574.

Smith, H. H. Extracts from the address at the annual meeting of the Pennsylvania State Medical Society, 481, 507.

Snow-shoes. Quick time on snow-shoes, 598.

Societies. American Medical Association, 425, 463, 473, 477, 489, 517; Boston Society for Medical Improvement, 104, 131, 183, 227, 271, 348, 397, 431, 495, 561; Boston Society for Medical Observation, 59, 84, 256, 308; Boston Society of the Medical Sciences, 419; Bowdoin Medical Alumni Association, 549; British Medical Association, 216; Connecticut State Medical Society, 611; Essex North District Medical Society, 181, 561; International Medical Congress, 216, 569; Laryngological Association, American, 491, 514; Massachusetts Medical Society, 157, 502, 570, 584, 590, 594; Massachusetts Medico-Legal Society, 182, 617; Medico-Psychological Society, Boston, 308; Neurological Association, American, 617; New York Academy of Medicine, 106, 178, 229, 299, 325, 373, 419, 443, 468, 536; New York County Medical Association, 107, 203, 445, 538; New York, Medical Society of the County of, 14, 231, 360, 353; New York Neurological Society, 101, 109; New York State Medical Association, 163, 277; New York, Medical Society of the State of, 158; Obstetrical Society of Boston, 61, 275, 448, 564, 591; Pennsylvania State Medical Society, 481, 582, 559; Philadelphia Clinical Society, 422, 516, 566; Philadelphia County Medical Society, 63; Philadelphia, Pathological Society of, 16, 37, 85, 136, 206, 371, 595; Rhode Island Medical Society, 26, 305, 616; Suffolk District Medical Society, 6, 36, 101, 134, 151, 156, 253, 272, 297, 298, 349, 467, 470, 514, 540, 609.

Spitzka, E. C. Paths of coördination, 231.

Stedman, C. E. A case of renal abscess, 591.

Stevens, E. H. Abdominal aneurism, 61.

Stille, A. The value of ethical codes for practitioners of medicine, 404.

Stone. The simulation of stone, 138.

Stricture. The treatment of gleet and gonorrheal stricture by Otis's method, Garland, G. M., 181.

Strong, C. P. An unusual obstetrical case, 30, 36.

Surgery. Fracture of the base of the skull, Hinsdale, G., 85; prevesical cellulitis following herniotomy; phlegmonous abscess, "sous-ombilicale," in Hertaux space; perinephritic abscess, Ingalls, W., 289, 297; three cases illustrating some points in the pathology of certain injuries of the shoulder-joint, Nancrede, C. B., 387.

Swan, C. W. Inhalation of ammonia, 497.

Swift, J. B. A case of face presentation with some remarks on the treatment of this class of cases, 293, 298.

Swine Plague. The discovery of the germ of swine plague, Salmon, D. E., 285.

Sylvestrini. The course of the fever in acute croupous pneumonia, 622.

Syphilis of the brain and membranes, Wood, H. C., 25; a case of cerebro-spinal syphilis, Post, A., 28; clinical aspects of cerebral syphilis, Wood, H. C., 196, 220; diagnosis and treatment of syphilis, Detmold, 205; chancre of the tonsils, Taylor, R. W., 537.

"Taxation" Theory of expert testimony, 546, 573.

Taylor, R. W. Chancre of the tonsils, 537.

Technology. The new building of the Massachusetts Institute of Technology, 502.

Temple, W. W. Poisoning by fumes of nitric acid, 496.

Terry, H. D. A case of tubal pregnancy, 37.

Terry, H. The treatment of puerperal fever, 303.

Testamentary Capacity, 560.

Testicle. Sarcoma of testicle, Schweinitz, G. de, 566.

Tilden, G. H. Report on dermatology, 413.

Time. A plea for consistency, 238.
Theory and Practice. Report on theory and practice of medicine, Shattuck, G. B., 240, 270.
Thomas, C. H. Downward displacement of the transverse colon; three cases, with autopsies, 1.
Thomas, T. G. The prevention and treatment of puerperal fever (Discussion), 178.
Thrombosis. Thrombosis and the conditions which favor its development, Brockway, C. H., 56.
Tobacco. The use of tobacco by boys, Otis, E. O., 99, 101.
Tonsilitis. The treatment of follicular tonsilitis, Garland, G. M., 103; De Blois, T. A., 514.
Tonsils. Chancre of the tonsils, Taylor, R. W., 537.
Tracheotomy. A year's experience in tracheotomy, Gay, G. W., 320.
Trance. "Trance" as a symptom of hysteria, 185.
Trichinosis. An epidemic of trichinosis, 358.
Trotter, Dr. Thomas, surgeon to the fleet, 306.
Trumbull, J. Letter from Valparaiso, 620.
Tubal Pregnancy. A case of tubal pregnancy, Terry, H., 37.
Tuberculosis. General tuberculosis of serous membranes, Hughes, W. E., 206; tubercular ulcers of intestines with perforation, Hughes, W. E., 206; secondary tuberculosis of the bladder, ureter, kidney, and suprarenal body, Hughes, W. E., 207; inoculation of tuberculosis, Verneuil, 238.
Tumors. Section of fibroma mammæ, MacConnell, W. G., 38; section of large spindle-celled sarcoma of lower jaw, MacConnell, W. G., 38.
Tuttle, G. T. Cases of melancholia, 77, 84.
Typhilitis and perityphlitis, Wheeler, L., 409.
Typhoid Fever. Transitory aphasia in typhoid fever, 162; ætiology of typhoid fever, Janeway, E. G., 203; the treatment of typhoid fever, 300; enteric fever in New Haven, Eliot, G., 361; an epidemic of typhoid fever at a summer hotel, Woodward, L. F., 364; contagiousness of typhoid, Cabaniss, T. T., 524; scarlatina coexistent with typhoid fever, Pinnock (Victoria), 526.

Umbilical Hæmorrhage, Gibb, J. S., 422; Richardson, W. L., 592.
Urethra. Periurethral phlegmon, Waterman, T., 392, 398; external urethrotomy, Wheelhouse's operation, Fifield, W. C. B., 398.
Urethrotomy. A fatal case of internal urethrotomy, Gay, G. W., 2, 6.
Urinary System. A fatal case of internal urethrotomy, Gay, G. W., 2, 6; nitro-glycerine and the chloride of gold and sodium in the treatment of albuminuria, Bartholow, R., 32; nephrectomy for the removal of cancerous or sarcomatous tumors of the kidney, Homans, J., 73; malignant disease of the kidney, Wheeler, W. G., 106; the simulation of stone, 138; foreign bodies removed from the œsophagus and the urethra, Gay, G. W., 157; amyloid kidneys, Hughes, W. E., 206; secondary tuberculosis of the bladder, ureter, kidney, and suprarenal body, Hughes, W. E., 207; anuria from compression of the ureters by cancerous disease, Minot, F., 227; suppression of urine treated with cantharides, Fifield, W. C. B., 271; a case of cystopyelitis or pyelo-cystitis coincident with pyelitis, Otis, E. O., 290, 297; the detection of albumen in urine, Fowler, G. B., 299; malignant disease of the bladder, Burge, W. J., 304; chronic retention of urine, Bowditch, H. I., 349; clinical lecture on a case of myxœdema, Edes, R. T., 385; periurethral phlegmon, Waterman, T., 392, 398; external urethrotomy, Wheelhouse's operation, Fifield, W. C. B., 398; multiple calculi in the bladder, Cabot, A. T., 398; diphtheritic perineal wound; chronic cystitis; bilateral incision of prostate for removal of stone; acute suppurative peritonitis; autopsy, Porter, C. B., 399; removal of a fragment of catheter from the bladder, Porter, C. B., 399; albuminuria, Griswold, G., 538; physiological albuminuria, Chateaubourg, 550; links of articulated catheter removed from the bladder, Warren, J. C., 560; a case of renal abscess, Stedman, C. E., 591; a case showing the effects of hot water on papillary tumors of the bladder, Baker, W. H., 593.
Utica. Restraint at the Utica Insane Asylum, 187.

Valparaiso. Letter from Valparaiso, Trumbull, J., 620.
Verneuil. Inoculation of tuberculosis, 238.
Version. Podalic version, and abdominal pressure upon the after-coming head, Green, C. M., 449.
Vickery, H. F. Artificial inflation of the colon with gas, 332.
Vivisection. Mitchell, S. W., 533.

Wadsworth, O. F. Three cases of homonymous hemianopia, 483, 495; recent progress in ophthalmology, 556.
Wall-papers. Poisonous wall-papers, 262.
Walton, G. L. Hysteria, as affected by removal of the ovaries, 529, 542.
Warren, J. C. A substitute for strapping the testicle and the treatment of hydrocele, 157; the healing of arteries after ligature, 418; links of articulated catheter removed from the bladder, 560.
Washington. Letters from Washington, 453, 477.
Wasting Palsy. A case of "wasting palsy" (partial), Read, G. M., 268.
Waterman, T. Periurethral phlegmon, 392, 398.
Waverly Convalescent Home, 525.
Weber, L. Locomotor ataxia and syphilis, 325.
Webber, S. G. Cases of lesion of the brain cortex attended with unilateral symptoms, 49, 60; multiple neuritis, 441.
Wendt, E. C. Note on the use of the menthol cone as an anodyne, 109.
Wheeler, L. Typhlitis and perityphlitis, 409.
Wheeler, W. G. Malignant disease of the kidney, 106; treatment of blood-poisoning following surgical operations, 271.
Whitney, W. F. Recent progress in pathology and pathological anatomy, 458, 462, 487; a case of actinomycosis in a heifer, 532, 545.
Wigglesworth, E. Pathological conditions of the skin following the internal use of borax, 404.
Willets, M. Puerperal case with numerous complications, 566.

DOWNWARD DISPLACEMENT OF THE TRANSVERSE COLON. THREE CASES, WITH AUTOPSIES.[1]

BY CHARLES HERMON THOMAS, M. D.,
Surgeon to the Philadelphia Hospital.

A DEFORMITY of the transverse colon, consisting in the elongation of that portion of the large intestine and its displacement downward in the form of a loop or festoon, has been observed by me in three instances in private practice. Autopsies were had in them all. In the first the most dependent portion of the gut was found midway between the umbilicus and the pubic symphysis; in the second it was deeply impacted in the cavity of the pelvis; and in the third it reached the level of the umbilicus.

A positive diagnosis was not made in any of the cases, although in two of them the striking clinical conditions present were studied with special care in association with experienced and highly skilled observers. In the second in order of occurrence, the relationship between it and the preceding one suddenly occurred to my mind, and was communicated to the operator while on our way to make the post-mortem examination. In the third case the actual condition present was strongly suspected before death. So that in both of these latter special precaution was used at the autopsies to avoid disturbing the relative position of the abdominal viscera until their location had been accurately determined.

The lesion here described seems to be of rare occurrence. Thus far I have failed to discover a single recorded case; and not until this paper was nearly completed was I able to find any published reference to the condition, however vague. Several months ago I asked the assistance of Dr. Formad, who informed me that in a series of autopsies, numbering over 2000, which he had made, he had not observed an instance of like character. He has also kindly sent me the following note: —

"UNIVERSITY OF PENNSYLVANIA,
December 15, 1882.

"DEAR DR. THOMAS, — . . . I looked very thoroughly through the literature of intestinal lesions, but did not meet any record of misplacement of the transverse colon.

"Very truly yours, H. F. FORMAD."

CASE I. Male, aged eighty years, a retired gentleman, came under my care August, 1874, as a patient of Dr. J. J. Levick, who had placed his practice in my charge during his vacation, and who informs me that there was no previous history of abdominal disease.

The symptoms present were extreme emaciation, feebleness, anorexia, and a profuse but fitful diarrhœa. The abdomen was retracted and somewhat tender upon pressure. There was no complaint of pain except at intervals of three or four hours when the diarrhœa had ceased for a time. Coincidently with the cessation of the diarrhœa a tumor about five inches long and two inches wide, of firm consistency, and visible on inspection, appeared beneath the thinned abdominal walls in a transverse position midway between the umbilicus and the symphysis pubis. The tumor persisted but an hour or so at a time, disappearing immediately upon the return of the diarrhœa. During the periods of continuance of the tumor the pain was so severe as to rapidly weaken the patient. This condition of alternate flux and painful tumefaction was repeated several times daily until death took place. During the attendance upon the case there were associated with me Dr. Albert H. Smith and a distinguished physician from another city — a near relative of the patient. With attention fully directed toward it, and after repeated observations, we were unable to frame a reasonable hypothesis as to the exact character and origin of the tumor. Death occurred September 12th, about three weeks from date of attack.

Autopsy. In the presence of Dr. Levick and the relative mentioned I made the abdominal section. To the former I am especially indebted for the specimen obtained, and which is still preserved.

Upon laying open the abdominal cavity the transverse colon was found to be greatly elongated and proportionately narrowed, the loculi being nearly obliterated, forming a loop open at the top similar to the letter U, the most dependent portion occupying the position of and constituting the tumor as above described, that is, the horizontal portion of the loop rested upon the small intestines, midway between the umbilicus and the pubic symphysis.

CASE II. Female, aged fifty-four years, a lady of delicate frame and refined habits of life, was under my charge for about ten months prior to her decease. During the greater portion of this period Dr. James H. Hutchinson was associated with me in the attendance. Dr. Charles K. Mills also saw her for me during my vacation. The patient had previously been attended by a homœopathic practitioner who had diagnosticated her condition as enlargement of the liver and stricture of the rectum. The latter supposed condition he had treated by the introduction of rectal bougies; this practice being afterward abandoned on account of the pain produced, and the lack of beneficial results.

Profound cerebrasthenia from other causes, with several months of delirium, and which finally led to a fatal result, served greatly to complicate the issues involved. The abdominal conditions which had been recognized from the beginning were thus either masked or placed entirely in abeyance during much of the time.

The more prominent symptoms recognized were: —

(1.) Pain, referred chiefly to the region of the liver and extending both upward and downward, which pain was aggravated by walking, and was described as of a dragging, tearing character, and which had existed for four years or more. It was very much relieved by the recumbent posture, and after some months spent mostly in bed almost entirely vanished.

(2.) Obstinate constipation, with indications of obstruction, even a liquid passage being voided with difficulty. The capacity of the rectum to retain enemata was also diminished to two ounces.

(3.) Two solid tumors, elongated in form and of the consistency of solid fæces, were discovered, located one on each side of the abdomen, and evidently just beneath the parietal structures. They were vertical in position, and about eight inches distant from and so parallel to each other, and were traced from the border of the ribs to within about two inches of the pelvic brim. This condition was observed but a few times, and at considerable intervals; at other times it was absent. The hypothesis was adopted that these masses

[1] Read before the Philadelphia County Medical Society, October 17, 1883.

were the ascending and descending colon, respectively, in a state of fæcal impaction.

Death occurred March 30, 1882, supervening upon a severe mental shock. An autopsy was made by Dr. William M. Gray two days later, Dr. Hutchinson and myself being present. To quote from Dr. Gray's notes: "Upon opening the abdomen found complete prolapse of the transverse colon. It was carried beneath the pubis and rested on the bladder. The large intestine was much narrowed, and was filled throughout with hard nodulated fæces; the meso-colon was absent, and the omentum, which was free from fat, was extremely atrophied; the rectum was normal, showing no evidence of stricture; the liver was of normal size, but upon microscopic examination showed marked cirrhosis."

Thus that which had appeared to be the ascending colon proved to be the descending limb of the displaced transverse colon, and that which had seemed to be the descending colon was shown to be the ascending limb of the same malformation.

The pain which had previously been felt in the region of the liver, and which had been relieved by recumbency, had manifestly been caused by the sharp flexure of the colon contiguous to it, and the rectal obstruction by the crowded condition of the pelvis produced by the invading loop of large intestine.

CASE III. Male, aged thirty years, a tailor's cutter, under attendance nine days prior to decease. The subject of advanced Bright's disease, with "hyaline, epithelial, and granular tube casts, also mucous cells, compound granule cells, and free oil globules," he was extremely exhausted thereby. He also complained of severe pain in the abdomen to the right of and slightly above the level of the umbilicus. Upon inspection and palpation of the part no enlargement or induration was discovered, but light percussion developed an intensely tympanitic sound confined to the region described. Misplacement of the transverse colon was suspected, and the region kept under observation for any evidences of fæcal impaction which might, but which did not, present. Death occurred suddenly, March 19, 1883. Autopsy two days later by Dr. William M. Gray, operator, Dr. William H. Burke and myself being present.

The following notes were made by Dr. Burke: . . . "Body rather emaciated, and showing signs of commencing decomposition. On opening abdomen absence of fat noted; omentum normal. Peritonæum showing traces of lymph and pus, in the pelvic region especially, but no general inflammation. Tranverse colon empty, distended with gas, and has a sharp flexure at its centre, bending obliquely downward and toward the right, to the level of the umbilicus, thence sharply upward to its normal position. Meso-colon intact and apparently normal except in length. No sign of fæcal obstruction at the point of flexure. Both kidneys scirrhotic; capsule adherent, and secreting structure destroyed."

Evidently the heightened tympany localized near the umbilicus, which had been previously recognized and ascribed to the presence there of a portion of the transverse colon misplaced, had in reality been so caused.

No adhesions of the displaced parts were found in any of the cases cited. The intestinal fault was probably not the cause of death in any of them. Taking them together, it will be seen that clinical conditions and post-mortem appearances agree in at least one important particular, namely, the location of the displaced intestine in contact with the anterior abdominal wall and below its normal site.

The normal anatomical relations of the colon have a special significance in the light of these cases from a diagnostic point of view. The ascending and descending portions of the colon are, normally, to be found in contact with the *posterior* or lumbar wall of the abdominal cavity, — behind the small intestines, — and are there bound closely down by reflections of the peritonæum. The transverse colon, on the contrary, is normally in contact with the *anterior* abdominal wall — in front of the small intestines — where it is loosely suspended by the transverse meso-colon, a structure of considerable length.

It therefore appears to be a practical impossibility for the vertical portions of the large intestine to become spontaneously misplaced anteriorly. But of the transverse colon, its displacement downwards, — in which changed position its relation of contact with the anterior abdominal wall is retained, — these cases show to be a condition of repeated occurrence.

Conclusions. (1.) Displacement of the transverse colon downward within the abdomen may be to any degree, partial or complete.

(2.) Such displacement will present as solid tumor if the bowel be in a state of fæcal impaction, or as a limited area of heightened resonance if the bowel be distended with gas; but in either case the displaced part is to be found *in contact with the anterior abdominal wall.*

(3.) The occurrence of intra-abdominal tumor situated below the normal site of the transverse colon, and having the same general configuration as the colon, such tumor being of a certain consistency, and presenting evidences of being in contact with the anterior abdominal wall, or the occurrence of areas of special typmpany with like outlines and similarly located, constitute diagnostic signs strongly indicative of downward displacement of the transverse colon.

A FATAL CASE OF INTERNAL URETHROTOMY.[1]

BY GEORGE W. GAY, M. D.

MR. D., aged twenty-three years, conductor, had had more or less difficulty in passing his urine for two years, having been obliged on several occasions to resort to a catheter. October 16, 1883, he was again seized with retention, which repeated efforts at catheterization failed to relieve. The bladder was finally aspirated above the pubes, and the patient sent to the City Hospital.

During the next three days he passed a fair amount of urine, the bloody character of which was supposed to be due to lesions of the urethra. His treatment consisted in rest in bed, diuretics and diluents, fomentations to the hypogastrium, and complete rest to the urethra. As the patient seemed to be in good condition, and it was evident from his history and from his very sensitive urethra that some more radical treatment was necessary, he was etherized and examined on the 19th of October. Five inches from the meatus was a stricture, which admitted only a fine whalebone

[1] Read before the Surgical Section of the Suffolk District Medical Society, November 7, 1883.

bougie; upon this a tunneled sound was passed through the obstruction; with a urethrotome the stricture was then carefully cut and dilated till a No. 25 steel sound passed quite easily. The hæmorrhage was unimportant. The immediate after-treatment was morphine hypodermically, large doses of quinine, fomentations to perinæum and abdomen, and liquid diet.

About six hours after the operation the patient had a chill, and on the following day there was complete suppression of urine. He was pulseless, delirious, had vomiting, high temperature, and a congested skin. He was put on infusion of digitalis, squills, and acetate of potash; fomentations of digitalis leaves to the abdomen; gin and cream of tartar for a drink; food and stimulants by the rectum.

Two days later the urine began to flow, but the nervous symptoms were not improved. Free catharsis was produced with elaterium, when there was a temporary change for the better in that respect. It was of short duration, however, and in spite of hot-air baths and a fair secretion of urine he became comatose, gradually failed, and died six days after the operation.

The autopsy was made by Dr. Gannett, and his report is as follows: —

"The first five inches of the urethra from the meatus showed nothing unusual. The next two and a half inches, extending to the prostatic portion, showed numerous rents in the mucous membrane parallel to the course of the urethra. The mucous membrane was here of a reddish-brown color, and was covered with a shreddy, diphtheritic false membrane. The surrounding corpus spongiosum was indurated.

"The bladder contained about two ounces of a thick, blood-red fluid. The muscular walls were doubled in thickness. The mucous membrane thickened, velvety, of a reddish-black color, in portions covered with a diphtheritic false membrane and fine, gritty material.

"The mucous membrane of the pelvis ot the kidney showed a few circumscribed patches of hæmorrhagic pyelitis. The kidneys were both enlarged, dark-red in color, with several opaque-gray lines extending from the cortex to the apices of the pyramids. Microscopically the kidneys showed cloudy swelling of the epithelium of the convoluted tubules, and extensive hæmorrhages into the tubules.

"The lesions were as follows: laceration of urethra, diphtheritic urethritis, hæmorrhagic-diphtheritic cystitis, pyelo-nephritis. Evidence of general septicæmia was found in the cloudy swelling of various organs."

Dr. Gannett's report, as well as the state of the organs shown you, prove that there was no extravasation, no abscess nor unusual inflammation about the seat of stricture; nor were the lesions consequent upon the operation more severe or more extensive than was to be expected. There were no false passages, no gangrenous patches nor sloughs in or about the urethra. There was simply a firm, dense stricture, which had been cut or torn (and from the local appearances no one could have told which); nor was there anything whatever to indicate that the operation had produced unusual violence, or had been followed by unusual local changes.

This patient died from acute pyelo-nephritis, septicæmia, and uræmia, the immediate and exciting cause of which was undoubtedly the operation. The predisposing causes were very probably the long-standing inflammation of the bladder and urethra, and the consequent irritation of the nervous system.

It may be said that this was a case for external rather than internal urethrotomy, and also that if less violence had been done to the urethra the result might have been different. I can only say that I have operated on a good many similar cases in precisely the same manner with good results. On the other hand, I once lost a strong and apparently healthy man from suppression of urine four days after a single and easy passage of a steel sound. Hence I cannot think that the fault was entirely in the operation.

RECENT PROGRESS IN OTOLOGY.

BY J. ORNE GREEN, M. D.

STATISTICS OF EAR DISEASE.

IN a painstaking article Bürkner[1] has brought together all of the statistics of ear diseases which he has been able to find, and analyzed and tabulated them as far as was possible. Although, like all figures, these give us but dry reading matter, they nevertheless, from the large number of cases, bring out many interesting facts. It should, however, be borne in mind that they are open to the objection of all similar medical statistics, in that the observations are made by many different persons of various degrees of ability, in many countries, and under various circumstances, so that we must hesitate to accept many of the tables as giving anything more than a distant approximation to the truth. For instance, under the causes of ear disease we find the percentage referred to scarlet fever, measles, small-pox, typhus, etc., given, but it is evident that unless such figures extended over many years for the same town, they would be somewhat variable, according to whether there had been epidemics of those diseases. Tables of results of treatment in public clinics are always open to doubt, if, for no other reason, on account of the difficulty of keeping the cases under observation for a length of time. Others of the tables are of undoubted value.

AGE.

Of 34,532 patients 22.4 per cent. were less than 15 years old.
Of 34,532 patients 59.3 per cent. were between 15 and 50 years old.
Of 34,532 patients 12.9 per cent. were over 50 years old.
Of 41,287 patients 77.8 per cent. were less than 15 years old.
Of 41,287 patients 22.2 per cent. were adults.

SEX.

Of 37,920 patients . . 60.3 per cent. were men.
Of 37,920 patients . 39.7 per cent. were women.

PART OF EAR AFFECTED.

Of 58,645 patients . . 25.5 per cent. external ear.
Of 58,645 patients . 66.9 per cent. middle ear.
Of 58,645 patients . . 7.6 per cent. inner ear.

This table, from eighteen different sources, in comparison with the older tables of Wilde and Kramer, is interesting as showing the tendency of modern investigation to find disease in the middle ear, and is the direct result of pathological study and improved methods of examination. The same thing has been noticed in the study of eye diseases.

WILDE'S TABLE.

Of 2330 patients . . 55.8 per cent. external ear.
Of 2330 patients . 39.5 per cent. middle ear.
Of 2330 patients . . 4.9 per cent. inner ear.

[1] Archiv für Ohrenheilkunde, vol. xx., p. 81.

KRAMER'S TABLE.

Of 300 patients	16.5 per cent. external ear.
Of 300 patients	47.3 per cent. middle ear.
Of 300 patients	36.2 per cent. internal ear.

A large and interesting table of the percentage of different diseases is given, based upon the observation at sixteen different clinics of 43,730 patients, but no résumé is possible, and we can only refer to the original.

WHICH EAR MOST FREQUENTLY AFFECTED.

Of 3255 patients	60.3 per cent. both ears.
Of 3255 patients	17.6 per cent. right ear only.
Of 3255 patients	22.1 per cent. left ear only.
Of 2242 patients	54.0 per cent. both ears.
Of 2242 patients	20.0 per cent. right ear only.
Of 2242 patients	26.0 per cent. left ear only.

SEASONS OF ACUTE DISEASE.

The absolute frequency of acute disease according to months was as follows in 478 acute diseases among 2242 patients: —

September	5.7 per cent.	January	8.6 per cent.
August	6.7 per cent.	June	9.0 per cent.
July	6.9 per cent.	December	9.0 per cent.
October	7.2 per cent.	February	9.9 per cent.
April	7.8 per cent.	March	10.3 per cent.
November	8.1 per cent.	May	10.8 per cent.

But the relative frequency, that is, the percentage of acute disease in the whole number in attendance for each month was: —

July	12.3 per cent.	November	22.5 per cent.
August	16.1 per cent.	April	25.0 per cent.
September	17.0 per cent.	March	25.2 per cent.
June	17.9 per cent.	February	26.5 per cent.
May	18.6 per cent.	January	29.7 per cent.
October	22.0 per cent.	December	37.7 per cent.

Bürkner's conclusions are as follows: —

(1.) The most frequent causes of ear diseases are colds, affections of the nose and naso-pharynx, and the acute infectious diseases.

(2.) The predisposition to ear disease increases from birth to the fortieth year, and then decreases.

(3.) Men are more frequently affected than women; the proportion being about three to two.

(4.) Of all diseases of the ear about twenty-five per cent. are of the external ear, sixty-seven per cent. of the middle ear, and eight per cent. of the inner ear.

(5.) The left ear is more frequently diseased than the right, the proportion being about five to four.

(6.) The acute middle-ear diseases are less common in summer than in winter.

(7.) Of all cases of ear disease in the polyclinics fifty-three per cent. were cured, thirty per cent. improved, seven per cent. unimproved, and 0.3 per cent. ended fatally.

PERFORATIONS OF SHRAPNELL'S MEMBRANE.

The inflammation, perforation, and ulceration of this small triangular portion of membrane lying above the short process of the hammer, to the serious nature of which attention was early called in this journal,[1] is the subject of two instructive articles[2] by Morpurgo and Hessler. Both authors acknowledge the serious nature of the disease on account of the difficulties of treating it successfully, and on account of its complications; both have found it a somewhat rare disease, each reporting eleven cases, although the proportion of cases to the whole number of patients seen is not given. But few such statistics can be found. Moos, in 126 perforations, found perforations of Shrapnell's membrane four times, and Marian in sixty-two cases of chronic purulent inflammation of the middle ear found one perforation of Shrapnell's membrane.

Morpurgo would divide the cases of the disease into two classes: those in which the pathological process is localized and confined to the upper cavity, and those in which the whole tympanum is involved. The different appearances of the disease on inspection are well described; the dry unswollen membrana tympani wholly destitute of polish; the marked prominence of the short process and manubrium and the basin-shaped, sunken drum-membrane; the variable size of the perforation from a small opening up to a loss of the whole membrana Shrapnelli, or even a still larger opening due to destructive caries of the upper osseous edge of the tympanum, which even allows the niche of the oval window, the Fallopian canal, and the prominence over the horizontal semicircular canal, to be seen.

A very marked characteristic is the frequent absence of a perforation whistle on inflation of the tympanum. In eighteen cases of the disease four only gave this perforation whistle. The explanation of this Morpurgo finds in the recent anatomical studies of Prussak and Politzer, which, although differing somewhat in their details, agree so far as to acknowledge a system of cavities in what has been called the superior pouch of the drum-membrane, which cavities communicate with the drum cavity only by a very narrow opening. This narrow opening becomes closed by the swelling and secretion accompanying the inflammation, and therefore no passage is afforded for air from the tympanum to the meatus, even although the whole of Shrapnell's membrane has been destroyed. Morpurgo has proven experimentally both that the cavity behind Shrapnell's membrane communicates, when in its normal condition, with the tympanum, and that when this cavity becomes inflamed such communication with the tympanum ceases. In fourte n cases in which Shrapnell's membrane was normal he made a small perforation, and in all of them obtained a perforation whistle on inflation; in one of these cases, where the perforation whistle was obtained immediately after the operation, a moderate inflammation followed, and no perforation whistle could then be obtained. After the wound had healed, and the inflammation had subsided, another perforation was made, and the perforation whistle again obtained.

Caries with resulting granulations and polypi are complications of the disease.

The diagnosis of a general or localized inflammation Morpurgo makes from ocular inspection. If an otorrhœa with perforation of Shrapnell's membrane exists, and inspection shows the drum-membrane in toto swollen and reddened, with the hammer indistinct, the inflammation is a general one of the whole tympanum. If inflammatory changes are, however, only seen in the neighborhood of Shrapnell's membrane, and the rest of the drum-membrane is unchanged, and no communication with the tympanum proper exists, as shown by inflation, the process is a localized one. If in a similar case the drum-membrane is sunken like a basin, its mobility greatly impaired, and a perforation whistle is absent, a general inflammation has existed, but has disappeared leaving more or less alteration in the tympanum. The degree of deafness Morpurgo does not

[1] Boston Medical and Surgical Journal, March 26, 1874.

[2] The Pathology and Therapy of Perforations of Shrapnell's Membrane, Morpurgo, Archiv für Ohrenheilkunde, vol. xix., p. 264, 1883. Ditto, Hessler, Archiv für Ohrenheilkunde, vol. xx., p. 121, 1883.

consider of value in differentiating between the general and the localized process.

The therapy of perforations of Shrapnell's membrane, or rather of purulent inflammations of the upper tympanic cavities, cannot be left to the patient. Intratympanal injections are absolutely necessary, as the common injections of the meatus wholly fail to remove the secretion. For this purpose Morpurgo uses Weber's tympanic catheters, and for a fluid a saturated watery solution of boracic acid. The natural perforation is often insufficient to allow a thorough evacuation of the retained secretion, and then Morpurgo recommends enlarging the opening in various directions, especially upwards, by incisions, thus freely exposing the complicated cavities above Prussak's pouch. As the most useful in the further treatment of the case, a combination of the disinfecting intratympanic injections with the alcohol treatment has been found the best, spiritus vini rectificatissimus with an equal quantity of distilled water injected by the tympanic catheter, and used as an ear-bath for a quarter of an hour twice daily. Polypoid growths and caries of the bone require their own proper treatment. In chronic cases of the disease Morpurgo has not had satisfactory results with powdered boracic acid after Bezold's method, but in an acute case this treatment gave a brilliant result.

In forty cases collected by Morpurgo polypoid growths were present in twenty-one. Six cases were acute, and in four of these the perforation closed rapidly; in two the disease became chronic. The remaining thirty-four were chronic, and in seven of these the perforation closed; in twenty-six no closure took place, or the result was unknown, and in one case death resulted from meningitis. The ages of the patients were as follows: —

Ten years old	1 case.
Between 11 and 20 years old	4 cases.
Between 21 and 30 years old	14 cases.
Between 31 and 40 years old	14 cases.
Between 41 and 50 years old	4 cases.
Between 51 and 60 years old	3 cases.

The duration of the disease varied from a few days to more than twenty years.

Hessler bases his article on the study of eleven cases in private practice, and agrees entirely with Morpurgo in the clinical symptoms and appearances which the latter has described. He found the disease in just one per cent. of all cases treated, and his youngest patient was but four years old. In all the cases the suppuration was slight in quantity, but always from the very beginning fetid. In six the head was free from the pressure and pain which often accompanies this form of inflammation, while in four there was long-continued and recurring pain and pressure on the same side as the ear disease. In nine the perforation was in the upper and anterior part of Shrapnell's membrane. In one it was in the posterior upper quadrant of the same membrane, while one was acute and had not been perforated. In only two cases was there a communication between the Eustachian tube and the suppuration, so that a perforation whistle could be obtained. As the results of treatment in four there was complete healing of the suppuration and closure of the perforation. In one the same result was probably reached. Two others were still under treatment, and two were unsuccessful.

The treatment of these cases Hessler considers must depend upon whether the suppuration can be reached only from the meatus, cases in which there is no communication with the tympanum proper, and consequently no perforation whistle, or whether it can be also reached from within, cases in which the tympanic communication exists. The latter are the most amenable to treatment, and he uses in them daily syringing with disinfecting solutions both from the meatus and from the Eustachian tube, and more stress is laid upon the thorough cleansing than upon the degree of concentration of the disinfectant. The use of powders he does not approve, as they are apt to hinder the evacuation of the secretion. Where caries exists the bone should be scraped with the sharp curette, and this should be followed by cauterization with silver nitrate or with the galvano-caustic. With caries of the head of the hammer the curette cannot be used, and the cauterization only can be applied. Galvano-caustic is preferred to the knife for enlarging the perforation when that is necessary, as the opening remains longer. The reaction from the galvano-caustic, although generally slight, is sometimes very marked, requiring suspension of the application for two or three weeks. Where such reaction does not take place the cauterization is repeated every six or eight days, and between times the thorough cleansing of the suppuration is continued daily. In case of exudation forming in the tympanum proper this should be evacuated by paracentesis. In this treatment by cauterization Hessler differs from Morpurgo, who thought his results were better from alcohol than from cauterization.

For the second class of cases, those in which there is only a communication with the meatus, but none with the tympanum, Hessler, not finding the results from disinfecting injections in the meatus and cauterization satisfactory, although they were not used with Weber's tympanic catheter, tried to convert them into cases of the first class by puncturing with the galvano-caustic in the upper and posterior part of the drum-membrane. In only one case, however, was he able to get the desired communication with the tympanum, and in that the daily disinfecting injections produced a cure.

PRESSURE IN THE TREATMENT OF BUBOES.

O. Petersen[1] treats buboes, after fluctuation is clearly determined, as follows: A large incision is made and the cavity of the abscess is cleaned out with a sharp spoon. The bleeding is stopped, and iodoform powder is applied. Then comes the pressure bandage, which is the important principle in this treatment, and its application is as follows: First a ball or wad of salicylic cotton or some soft, pliable material, made antiseptic with salicylic acid, is formed of the size of the cavity, and placed over it; upon this wad are then placed several layers of the same material; then a second ball or wad made of tow or oakum, and about four times as large as the first, is placed upon this. Over this oil-silk or wax-paper, and the whole is firmly fastened with a gauze or elastic bandage. This bandage remains unmolested, as a rule, from seven to ten days. The average length of healing, in a trial for three years of this method, was twenty-three days; previously the average was from seventy to ninety days. Twenty per cent. of the cases healed under one bandage, twenty-five under two, twenty under three; more than seven bandages were in no case necessary. The average number of bandages was two.

New Instruments.

A NEW HIP SPLINT.

BY A. T. CABOT, M. D.

THE splint which I shall describe has been in pretty constant use at the Boston Children's Hospital for several years. It is easily made, is very efficient, can be adapted to a variety of conditions, and costs but little.

The foundation material is a wire rod from three sixteenths to one fourth of an inch in diameter, which can be readily bent with wrenches or in a vise to the form shown in Fig. 1.

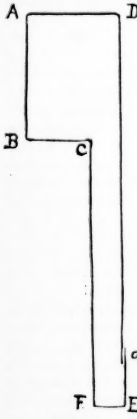

FIG. 1.

The free ends are then lashed together with copper wire at *a*.

The measurements required are:

D E. From the axilla to a point one or two inches below the heel; or if desired the splint may be finished to reach only to just below the middle of the calf.

A D. The width of the trunk.

A B. From the axilla to a point midway between the crest of the ilium and the top of the trochanter.

F E. Two to two and a half inches, according to the size of the leg.

A D and B C are then to be bent to conform to the curve of the back; it being particularly important that B C shall be sufficiently curved to jump across the sacrum without exerting injurious pressure upon it. Lastly, the rods running longitudinally are to be bent so as to adapt themselves accurately to the curves of the back, hip, and knee.

This frame, especially in those parts which cross the body, is to be thickly wound with strips of cotton batting, and the whole covered with Canton flannel tightly stretched across it. Lastly a swathe is to be stitched onto the body part of the splint (A B C D).

After the frame is accurately fitted to the curves of the body the patient is to be laid upon it, so that point B takes its bearing on the gluteus muscle of the well side, and C rests a little outside the sacro-iliac synchondrosis on the affected side. The pressure of the splint is thus borne by parts well padded with muscles, and if B C is sufficiently curved the sacrum and surrounding bony prominences are not pressed upon. It is, however, a good precaution to put a large sheet of cotton batting upon the splint to still further protect against the danger of a bed sore.

The frame being accurately adjusted the swathe is to be pinned firmly round the body, and the leg is bandaged to the leg part of the splint.

When applied as I have described, the splint fits the patient comfortably but firmly, and as it leaves a considerable interval between the anus and any part of itself, it can be kept clean, and consequently can be worn for a long time without changing.

Besides its use in hip disease, this splint is of value in the treatment of fractured thigh in children. With

FIG. 2.

coaptation splints to the sides and front of the thigh, and with a foot piece, Fig. 2, added to the splint to prevent the rolling of the foot to one side or the other, we have perfect immobility of the fractured bone, and are able to move and handle the child with entire freedom, and without causing the least pain. Another obvious application is to cases of excision of the hip. Here again we need a foot piece to prevent rotation of the leg, and the wires where they pass behind the hip are divested of padding and can then be thoroughly cleansed and included in an antiseptic dressing. The splint has been so used in several cases of excision with satisfaction. The patients were free from pain and were easily moved. One child, indeed, was carried from Boston to Nova Scotia while the wound was far from well without discomfort or apparent detriment to the joint. If it is desired to combine extension with fixation, it can be done by fastening to the outer rod D E an arm coming forward and curving round the side just below the crest of the ilium. By a buckle attached to the top of this arm, and another behind the splint, a band can be carried through the perinæum. At the end of the leg of the splint are then to be attached two buckles through which the extension straps can be drawn and held down, or if desired an arrangement with a ratchet and pinion fastened to the foot of the splint will provide for more steadiness of extension.

Lastly, this frame, if fitted to reach only to the middle of the lower leg, can be used like a Thomas' hip splint in the ambulatory treatment of hip disease, the patient walking about with a high shoe on the well foot and crutches.

It would seem at first sight that the splint would interfere with the patient's sitting down, but practically, if the body part is not made too wide, the splint is not more uncomfortable than a Thomas' splint in this respect, and it has the decided advantage that it is less likely to be displaced.

SURGICAL SECTION.

S. J. MIXTER, M. D., SECRETARY.

NOVEMBER 7, 1883. DR. G. W. GAY reported

A FATAL CASE OF INTERNAL URETHROTOMY.[1]

DR. GANNETT exhibited the specimen, consisting of the whole urinary tract of Dr. Gay's patient.

DR. A. T. CABOT asked Dr. Gay whether he did not think that a catheter left in the bladder immediately after the operation would, by providing for a free escape of the urine, have diminished the danger of death from suppression in this case. Dr. Cabot also asked if the result in this case would cause the reader to adopt some other method of operating in similar cases in future.

DR. GAY said that in such an unfavorable case for operation he should be inclined to do external urethrotomy, though it is an operation to be avoided if possible, as it often leaves the patient with urinary fistulæ, and necessitates a much longer after-treatment than the

[1] See page 2 of this number of the JOURNAL.

internal treatment. It is, perhaps, well to risk some thing in doubtful cases. The reader had since per formed internal urethrotomy in a case of stricture two inches from the meatus, the operation being followed by quite severe symptoms for forty-eight hours. The reader and all the other surgeons at the City Hospital had for some years abandoned the practice of leaving a catheter in the bladder after divulsion or internal urethrotomy, as they considered that it rather diminished than increased the chance of a favorable result.

In reply to a question by Dr. Watson, the reader said that the danger to life was decidedly greater in the internal than in the external operation. After the latter there is almost no fear of abscess, pyæmia, or other septic processes.

In reply to a question by Dr. Garland, Dr. Gay said there was almost no conceivable condition of the urinary tract where the surgeon should refrain from operating by some method to relieve symptoms of retention and stricture as severe as were present in this case. It is of primary importance to relieve the stricture, as that is the cause of the whole trouble, and must be removed before a change for the better in the bladder and kidneys can be hoped for. When, however, the symptoms were not severe, and the stricture could be kept well open by means of gradual dilatation, he was of the opinion that any operation should be avoided.

DR. GANNETT said that the changes seen in the bladder in this case were ante-mortem, and due to the long-standing cystitis caused by the stricture, while the pyelo-nephritis and diphtheritic inflammation of urethra and bladder followed the operation, the process spreading from the lower to the upper part of the urinary tract, probably by means of micro-organisms which passed up the ureter, and which may have been present in the bladder for some time. In cases where the kidneys are infected in this way the inflammatory process often skips from the bladder to the pelvis without manifesting its presence in the ureters.

DR. CHEEVER called especial attention to the much greater safety of the external operation of urethrotomy, which almost always gives a good result as regards the life of the patient, although it is usually adopted only in the most severe cases. After this operation the bladder is allowed to empty itself in the easiest possible manner, and perfect drainage is permitted.

The subject for discussion was

EXCISION IN HIP DISEASE; ARE ITS PROGNOSIS AND ITS RESULTS BETTER THAN THOSE OF A SPONTANEOUS CURE.

DR. E. H. BRADFORD, in opening the discussion, said that it was impossible at present to deduce from the facts as yet presented exact surgical laws regulating excision, and cases will have to be judged chiefly according to their individual merits. Certain facts, however, have been collected justifying some generalizations of value, which may be grouped as follows: —

(1.) As to the immediate danger from the operation.

(2.) As to the chance of ultimate recovery after the operation.

(3.) As to the usefulness of the limb after such recovery, and the time required before such a result is gained.

(4.) As to the probability of and requisite length of time for a "natural" cure, and the subsequent usefulness of the limb.

It may be said as a preface that this consideration of the subject is limited to cases of hip disease, and chiefly of children under puberty.

I. There can be little doubt that among the grave surgical procedures excision of the hip cannot be considered an extremely dangerous one. The rate of mortality directly due to the operation, according to the report of the London Clinical Society's Committee, is fifteen per cent.[1] According to Culbertson the mortality from partial excision is nineteen per cent., and from complete excision thirteen per cent.[2]

II. Forty-six per cent. of the cases of complete excision collected by Culbertson, and forty-three per cent. of partial excision, died within six months of the operation.[3] According to the London Clinical Society the mortality was, in 320 cases, forty per cent.[4] Antiseptic surgery would appear to have lessened the rate of mortality, for Grosch, in 126 cases of the operation done under the strictest antiseptic precautions, reports a mortality of 36.7 per cent., and that in the last half of the decade during which the list of operations was collected the mortality was nine per cent. less than in the first half of that period, during which an apprenticeship to strict antiseptic principles was being served. The mortality also varies according to the stage of the disease at which the operation is performed, being 0 at the first stage, twenty-four per cent. at the second, and sixty-seven at the third.[5]

III. It would appear from the clinical facts presented by Mr. Holmes that the limb after the most successful excision is not as useful as after a "natural" cure,[6] This is emphatically the opinion of the London Clinical Society,[7] and this view is apparently substantiated by a comparison between the anatomical appearances in the few reported cases of autopsy after successful excision with those found in a natural cure.[8] The process of absorption and repair in the natural cure is a gradual one, and the bone becomes firmly welded in place by the slow deposits of the ossifying ostitis which follows the destructive ostitis of the original disease; only such portion of the bone is removed as cannot be saved, and the fragment of the neck and head becomes well surrounded and securely held in an acetabulum gradually altered in the successive processes of disease and repair. After excision, on the contrary, a large fragment of bone is removed, and the subsequent union with the ilium in the most successful cases is by ligamentous and fibrous bands, forming in some cases a false capsule, and if ossification ultimately takes place it can hardly be thought that the parts will be as accurately fitted as is the case after the more gradual process. A flail joint at the hip, or one approaching it, is certainly not so useful as a stiff joint. Cases which appear to be cured sometimes are ultimately not as satisfactory in the result as was at first considered probable. Case 464, Culbert-

[2] Trans. of American Medical Association, 1876.
[3] Culbertson does not consider many of these deaths (that is, twenty-six per cent. of them) as attributable to excision, and classifies them as due to "other causes." A list of the diseases, however, makes it clear that this is hardly just; bed sores, amyloid disease, Bright's disease, meningitis, are all to be considered in estimating the chances of ultimate cure. According to the London Clinical Society about four per cent. of the deaths were due to causes other than the disease and not influenced by the operation.

son's Table, was reported as perfectly cured, and three years later was found in a permanently crippled condition, with a useless limb.[1] Furthermore it has not been found that antiseptic dressings have any influence upon making the limb ultimately more useful, or upon the length of time necessary for a permanent cure. This, according to the London Clinical Society, is one and three quarter years; according to Culbertson 190 days. It is manifest, however, that it is difficult to obtain figures of great value bearing upon this point.

IV. In comparison with these figures Dr. Gibney reports the results of "natural" cure to be as follows: Eighty cases of recovery were recorded; no particular treatment being followed beyond constitutional (forty-eight of these had abscesses); cure was established in seventy-one of these before the fifteenth year, the disease lasting, in thirty-three, three years; in twenty-eight from three to six years; and in one case fifteen years. In only eight of these cases did such a deformity exist as to interfere with walking. Out of the eighty cases, in twelve there was a recovery in motion of from fifteen to ninety degrees.[2] Better results are of course obtained, as far as the usefulness of the limb is concerned, where careful and continued treatment can be carried out for a long time than where the limb is practically left to itself. The results reported by Dr. Judson[3] clearly demonstrate this, as well as that remarkable results can be obtained even in desperate cases by the conservative treatment. Cazin found in five years that in eighty cases of suppurative hip disease treated by the expectant plan —

Forty-four were cured (fifty-five per cent.).
Twenty not cured (thirty-three per cent.).
Ten died (twelve per cent.).

Of these fifteen were complicated by albuminuria, and five died, six were not improved, two were improved, two were cured.[4]

The mortality, according to the London Clinical Society, in suppurative cases treated conservatively was thirty-three per cent.; forty-two per cent. were known to be cured, and the duration of treatment of those who recovered was two and a half years, the duration of the disease being four years. In non-suppurative cases sixty-nine per cent. were cured (the duration of the disease being three years), ten per cent. died, and twenty per cent. remained incomplete.

Taking the facts, imperfectly recorded as they are as yet, it may be roughly stated that in one hundred average cases of excision about forty die, and of those who recover about twenty-five will have limbs that they can walk on without a cane, twenty-five will need a cane or crutch, and five will have limbs that are useless. The limbs will probably not be as useful as if the patients had survived the disease with the average result of a "natural" cure, the chances for which in an average suppurative case may be placed roughly at fifty in one hundred. The time required for a cure after the operation will be probably somewhat less than if no operation is performed.

Recurring again to statistics and quoting from Culbertson: nearly a half of those who recovered from the operation had "perfect" limbs (that is, they could walk without support); about the same number had "useful" limbs, and could walk with and without apparatus; five to seven per cent. had worthless limbs. Out of some eighteen cases Mr. Holmes was able to examine three from eleven to thirteen years after the operation, and but one was able to bear the whole weight upon the affected limb. It may be said, therefore, that excision of the hip is a measure to be resorted to only as a last resort and as a life-saving remedy, and is indicated in cases of profuse suppuration and continued loss of strength in spite of thorough treatment for some time, as well as in cases where the course of the temperature indicates a demand for complete drainage. Mr. Holmes has expressed the matter well as follows: "The operation has a claim for adoption from its success in saving life where natural cure seems improbable. These cases are rare, if care for years can be provided."

DR. A. T. CABOT said that he regarded excision of the joint in hip disease as a life-saving operation, to be resorted to only when recovery by the natural powers is manifestly impossible. Cure by anchylosis is the most favorable result which can follow an extensive caries of the head of the femur, and the pelvis adapts itself so readily to the changed condition of things that a patient with the hip anchylosed in a good position has a very serviceable limb upon which he can walk with often but a slight limp. As Dr. Bradford has just shown, the fibrous articulation frequently resulting from an excision is, in the majority of cases, far less useful than an anchylosed joint, so that the best result of excision is no better than that which follows spontaneous cure, and the limb is necessarily shortened by the length of bone removed.

In a severe case of hip disease, then, the first thing is to fix the joint with an appropriate apparatus and to use every effort to promote bony union. If abscesses form they should be freely opened, the tubercular lining membrane should be thoroughly scraped out, sinuses should be followed up and curetted, and any rough bone which is reached should be removed. Counter-openings should be made, if possible, behind the hip-joint so that they may be dependent, and secure thorough drainage. Abscesses treated in this way heal much more readily than after a simple opening.

If in spite of all care the patient steadily loses ground, and suffers continuously from hectic, particularly if pain in the hip is a prominent and distressing symptom, then the removal of the diseased head of the femur and of the tubercular material about the joint is demanded.

As cure by anchylosis is the result to be sought it is of the greatest importance to apply an apparatus after excision which shall provide for perfect fixation, and which shall allow the dressings to be changed without movement of the joint.

Dr. Cabot showed a splint which he had used upon four cases of excision with entire satisfaction, and which is fully described in another part of this journal.

DR. GANNETT showed a section from a tuberculous joint in which the tubercles were plainly visible with a lens of low power, and spoke of the tendency of the process to become general throughout the body unless it yielded to proper treatment.

DR. CABOT said that, as Dr. Gannett had shown, the disease was to a great extent a morbid growth, which tended to recur if not fully removed unless the natural powers of the patient were great enough to resist its further progress. In case, therefore, that the

[3] History of Three Cases of Hip Disease in the Third Stage.
[4] Bull. de la Soc. de Chir., No. 5, 1876.

sinuses continued to discharge freely for a long time it would be a wise course to follow them up by a second operation, and again, with a sharp spoon, scrape out all granulation tissue which could be found either in the soft parts or in the bones.

DR. ROYAL WHITMAN showed a patient of Dr. C. D. Homans whose right hip had been excised nineteen months before.

The patient entered the City Hospital October 4, 1878, at the age of four, with a history of a fall six months previously, which was followed by gradually increasing pain and lameness.

The examination showed an obliteration of the right gluteo-femoral fold, moderate flexion of the thigh upon the abdomen, and considerable limitation of motion on the affected side.

He was treated by rest in bed with extension, and left the hospital six months later, wearing a Sayre's short splint.

In October, 1880, he entered the hospital, the symptoms being about the same as on his last admission. He remained there for two months, and the acute symptoms having subsided, he was discharged. On October 11, 1881, he again entered the hospital, with a history of a fall followed by pain and increasing disability.

The examination showed the leg to be flexed almost at right angles to the body. Dr. Bradford, under ether, forcibly extended the leg, and the child was placed in bed with eight pounds' extension. He remained in the hospital for three months, and was then discharged, on crutches, wearing a high shoe. At that time the leg was straight, and there was considerable motion in the joint. On January 31, 1882, he entered the hospital for the fourth time, with the usual history.

Examination showed pain on motion, obliteration of the gluteo-femoral fold, moderate flexion and fixation of the joint, with a hard, elastic semi-fluctuating swelling in the groin. He was placed in bed, and a T splint and extension were applied.

At the end of three months, as there had been no improvement in the symptoms, Dr. C. D. Homans decided to excise the hip, which was accordingly done on April 10th, 1882, the head of the bone being removed at a point two inches below the trochanter, and the acetabulum, which was found to be roughened, was thoroughly scraped. Very little shock followed the operation, and there was an immediate improvement in the condition of the patient.

After the operation the patient was placed upon a frame, moderate extension applied, and the leg kept in a fixed position. The wound was dressed with iodoform and salicylic cotton. The patient was discharged February 5, 1883, the wound having completely closed. Since this time his health has been perfect.

At the present time examination shows the following result: The leg is somewhat smaller than the other, and there are two and one half inches shortening. The head of the bone appears to be in close apposition to the acetabulum. The wound has completely closed, and there is no pain or tenderness about the seat of the operation. A certain amount of limited motion still remains at the joint. The patient walks easily, with a considerable limp from the shortening. If the body is steadied he can support his weight upon the limb without discomfort.

DR. CHEEVER regretted the absence of many of the older surgeons who had had such a large experience in the treatment of these cases, and spoke especially of the good work done by Dr. Buckminster Brown in this field. Fifteen years ago, when almost all authorities favored excision, Dr. Brown predicted that the opinion in regard to the operation would be greatly modified in time, and that it would be reserved for carefully selected cases. At that time the traumatic or constitutional origin of the disease was in dispute, but now almost all cases are regarded as the results of a tuberculous process.

It seems to be true that if a patient with hip disease does not recover before puberty the result is generally fatal. Dr. Cheever spoke of a patient who died at the age of twenty-two of hip disease that began in early childhood. Before death there were extensive sinuses about the joint and thigh, and the process had extended across the pelvis and in every direction until both sides of the pelvis, both nates, the sides of the abdomen, and even the thoracic wall, as well as the rectum, were the seat of extensive suppurative processes.

On the other hand patients may recover the use of the limb and fairly good health, though there may be occasional relapses. One patient, an active business man, wears a splint, and is quite well, though occasionally, if he remains in this cold climate in winter, abscesses form about the seat of the old disease. Another similar case is that of a young lady, who is quite well except for an occasional small abscess. These cases were treated without operation. Another case in which excision was performed was seen thirteen years after the operation with extensive sinuses, and in all respects as badly off as, though he had never been treated.

Constitutional treatment is all important. Fresh air and nourishing food are absolutely necessary, and often these alone seem to effect a cure. At Rainsford Island Hospital many cases of hip disease were formerly received; many in a very reduced and wretched state. These received little treatment beside plenty of plain, wholesome food and plenty of fresh sea air, and the number of recoveries was remarkable. It is often difficult to decide whether there is a loose sequestrum in the joint, though bare bone can be easily recognized. Bony crepitus is not always obtained after etherizing, as the joint is filled with granulations. No one doubts that excision is the proper treatment in desperate cases; but it should be borne in mind that the disease is apt to recur in the shaft of the femur after the head has been excised; that the limb after a spontaneous cure is almost always stronger; and that there is less shortening and greater power of eversion than after excision. If openings are made they should be large, and free drainage should be encouraged.

DR. BRADFORD spoke of the peculiar liability of children with hip disease to carbolic poisoning, and mentioned a case where the drip was employed after excision, the death of the patient being undoubtedly due to carbolic absorption. No bad effects have been noticed in a large series of reported cases where a solution of corrosive sublimate had been used, except slight diarrhœa in two cases, supposed to be due to absorption.

DR. CABOT spoke of the beneficial effect of iodoform in the treatment of local tuberculosis, it having almost a specific action upon the tuberculous granulations. He had used it in comparatively small quantities, dusting it on and injecting it in oily solutions.

NEW YORK NEUROLOGICAL SOCIETY.

REGULAR meeting of December 4, 1883. DR. WILLIAM J. NORTON, President, in the chair.

DR. GEORGE W. JACOBY read a paper upon

NEUROTIC AFFECTIONS ACCOMPANYING JOINT LESIONS.

The history of the subject goes back as far as Hippocrates, by whom it is mentioned. John Hunter was the next to take any note of it, and it is with him that originated the sympathetic theory. Malgaigne, 1826, and within the last ten years, Weir Mitchell, Duchenne, Verneuil, Sir James Paget, and Charcot and his pupils, comprise the list of names that have cast light upon the subject. The experiments of Valtat show conclusively that as a result of injury to the articular or even to the periarticular tissues produced by irritant injections the muscles of the entire limb, but more particularly the extensors of the joint, become atrophied. The result of the experiment given in the paper, as shown by the autopsy, is that the extremity which was experimented upon lost eighty grammes in weight in twelve days, and that each and every muscle separately weighed less than its corresponding fellow of the left side.

The affections which most frequently follow joint disorders are paralysis and atrophy of the muscles and hyperplasia of the subcutaneous connective tissues. More uncommon are anæsthesia, hyperæsthesia, analgesia, hyperalgesia, and neuralgias.

Three groups of nerve functions are implicated: motility, sensation, and nutrition. Symptoms are, after the joint lesions, a change in the appearance of the limb. The extensor muscles are generally the ones involved.

There is a change in the electrical reaction of the muscles, their contractile power is diminished, and finally lost. There is no reaction of nerve degeneration, no reversion of the normal contraction formula. This is also most noticeable in the extensors. The paralysis may appear as early as twenty-four hours after the accident; may also appear very late. The hypertrophy of subcutaneous connective tissue seems to stand in a direct ratio to the atrophy of muscular substance. The atrophy is ascending and progressive. Contracture is rare. The disorders of sensation are early symptoms, and differential diagnosis between these affections and progressive muscular atrophy may become difficult.

The conclusions which I am entitled to draw from the notes of thirty cases are: First. That in all cases except those involving the ankle or wrist-joint the muscles affected were the extensors of the diseased articulation. Second. That in those cases which involve the ankle or wrist-joint the affection is descending instead of ascending, and that the extensors are not affected to any greater extent than the other muscles. Third. That in cases of arthritis of any of the joints of the fingers the interossei muscles suffered first and most.

The cases which present particular interest are the following: —

CASE I. Mrs. L., age thirty-four, while walking, slipped and fell, striking her right knee. The joint rapidly increased in size, and was very painful. The following day it was very much enlarged, the patella pushed forward, and fluctuation was distinctly noticeable. The joint affection improved rapidly, but upon the seventh day a distinct paralysis was noticeable. The movement of flexion of the leg upon the thigh was easily executed, but that of extension was performed with great difficulty. Patient could only by the strongest effort produce any contraction of the triceps cruris. As the effusion became absorbed the paralysis increased, and at the end of three weeks it was impossible for her to extend the leg at all. Atrophy was now well marked, showing a difference of three centimetres in favor of the healthy limb. The gluteal muscles were also involved. The electro-contractility of the muscles was decreased to both currents.

CASE II. This case shows how soon after the injury paralysis and atrophy may ensue.

Patient, a laborer, age thirty-four, was struck upon the left knee on a Friday afternoon. He applied ice to the joint. The swelling went down. I saw him upon the following Monday, seventy-two hours after the injury, and then a distinct paralysis of the triceps cruris was noticeable, and atrophy was distinguishable upon the following Friday.

CASE III. By this case may be seen how entirely disproportionate the effect may be to the cause.

Patient, L. H., merchant, age thirty. While walking his left ankle-joint turned, the outer margin resting upon the ground. Notwithstanding severe pain he continued his walk. Used the joint for several hours. When he examined his foot he did not notice any change in the appearance, but it was painful on pressure. After two months he noticed a slight weakness in the injured leg, which was particularly observable upon going down stairs. Four months after the accident I saw him. His condition was then as follows: His foot hangs with the toes pointing downward, and cannot be brought to a right angle with the leg. He walks upon his toes, and does not bring his heel to the ground. The toes may be easily raised, but they fall back again by their own weight. The interossei of the foot are atrophied. The peroneal muscles, the muscles of the thigh, are also involved. The gluteus maximus is evidently considerably atrophied, for a large depression takes the place of its former prominence. Added to this severe neuralgia of the sciatic and peroneal nerves rendered a condition almost unendurable.

The pathogenesis of the affection is still a disputed one. The sympathetic of Hunter, the pressure theory of various writers, the theory of functional inertia, then that of Vulpian, which is reflex, and finally those of Decosse and Charcot, are all incapable of satisfactorily explaining all of the cases.

The treatment, in order to be successful, must be varied and adapted to each special case. The chief agents at our disposal are: electricity, massage, mechanotherapic and hydrotherapic in the form of hot and cold douches. Massage in very many cases seems to deserve preference to the electrical currents. The effects producible by massage are: —

(1.) The diffusion of any articular effusion. (2.) The comminution of vegetation. (3.) The loosening and destruction of adhesion. (4.) Increase of circulation. (5.) Stimulation of muscular fibres.

In fact, all the agents above mentioned seem to act similarly by stimulating the nutrition of the affected muscles, by increasing the flow of blood to the parts, and perhaps thus causing a reflex excitability of the motor tracts.

After reading the paper the subject was thrown open for discussion. Dr. Charles Fayette Taylor said: This is a subject with which I have considerable familiarity, as all persons who are extensively engaged in the treatment of joint affections must have, but it is too large to even touch upon in many of its aspects, in the limited time at my disposal to-night, even if I had prepared myself for such a discussion by having previous intimation of the direction it would take. I should prefer to have the subject arranged before speaking of it, especially as I shall be obliged to differ from the essayist, both as to the pathology and treatment of the neurotic disturbances attending or following joint diseases of the character which he has set forth in the paper. In regard to the pathogenesis, I do not think it is necessary to adopt any peculiar theory, or to assume that even any special deviation from the ordinary course of nerve function takes place in order to account for all the facts observed in these cases. The difference is one of degree only. A person is attacked with inflammation of the knee-joint, for instance; this is rapidly followed by diminished size of the muscles controlling the action of that joint, with diminished and sometimes even with entire loss of muscular action. But loss of muscular action is by no means evidence of loss of muscular power. The nerve centres are unquestionably affected; but, most of all, the cerebral nerve centres are the seat of the greatest disturbance. No theory can be adequate which leaves the cerebral nerve centres out of the account, and the consequent mental element which plays, in my opinion, so important a part in these cases. The simple loss of muscular action, consequent on an attack of inflammation of the knee-joint, is sufficient to account for an immediate diminution of the size of the muscles whose freedom is curtailed. This is the certain result from mechanical restraint alone. But if, besides the mechanical restraint of position or retaining apparatus, there is added the mental restraint of fear, the difference in the rate and amount of muscular atrophy is enormously increased. Mental restraint acts similarly to an Esmarch's bandage; it squeezes the very life out of a muscle. As a very simple proof of the remarkable effect of mental restraint in causing muscular atrophy, let me mention those frequent instances accompanying disease of the hip-joint. These cases often apply with limbs attenuated to the last degree. That a large portion of the muscular attenuation, accompanying somewhat long standing hip-joint disease, is due to the mental restraint of motion, which might cause suffering, is proven by the fact that the application of proper mechanical protection, by which the mind is relieved of the fear of pain, is followed by immediate increase of muscular growth. This is so common and well-known a fact that advantage is constantly taken of it in the management of cases. My observation of the effects on the muscles of joint diseases must amount to some thousands of cases, and I never saw a case of atrophy which, in my opinion, could not be perfectly explained by non-use and mental restraint.

In regard to the therapeutics of muscular atrophy and loss of action following joint disease, I fear I must differ from the essayist quite as widely as in its pathogenesis. So far as the muscular wasting has been caused by non-use, during the progress of the arthritis, it is sufficient to set them to work again, after the inflammation has subsided. And, I may say, in passing, that muscles stubbornly refuse to act, or if forced to act, they as stubbornly refuse to develop during the progress of an arthritis. You must wait until the joint is well before you can expect the muscles to act readily enough, after there is no longer any joint affection, except for the restraint which is often maintained for a long time by mental impressions formed during the progress of the arthritis. It is astonishing to notice how deep and lasting the impressions made on the cerebral nerve centres may sometimes be. Whatever the treatment may be, I do not believe it can be of any direct service so long as there continues a mental restraint over the muscles; and it is equally true that whatever will remove such mental restraint will cure the atrophy. So important do we, in our practice, consider the mental influence over the muscles, attending and following joint diseases, that we take special pains to get and to keep the direction of that influence, for the very purpose of hastening the recovery of the muscular power, after curing the joint disease. But the object of treatment should be to divert the mind from the affected member rather than to keep up attention to it by local treatment. It is true that massage will sometimes seem to do much good to the atrophied muscles; but this is apparent and indirect rather than real and direct. Massage has elements of mental diversion and control, which may be properly and usefully employed. But, with a large experience in its use, I am free to say that I think it is very much overestimated as a direct therapeutic agency. Its direct effect on the muscles is very slight, and what there is is not exercise. Exercise involves nerve action as the initial force. Massage merely assumes to promote the forward displacement of a certain small portion of the tissue fluids. But such propulsion of the fluids contained in the soft parts, even if effected, is not exercise nor a rational substitute for exercise. Only by the legitimate use of the nerve centres, especially of the cerebral nerve centres, can there be any action deserving the name of exercise. To regulate such nerve centre function, when disturbed by the strong impressions made by joint inflammation, is the indication presented in the cases under discussion. In most cases time alone is sufficient. In others, any means which effects a diversion of attention, whether done to the affected member or at a distance from it (which is the safer plan), will effect a cure. Incidentally, massage, electricity, the manipulations of the so-called "bone-setters," as well as the "animal magnetism" of the more arrant quacks, all do appear to produce wonderful results in a certain number of cases. The results are real, but are not produced through any direct effect on the parts, but through the incidental impressions made on the cerebral nerve centres; that is, on the mind. The worst of it is that in a large number of these cases direct treatment to the part affected by the mental restraint tends to increase the mental impressions, and to indefinitely postpone that unrestrained action of the muscles by which alone they can regain their power. The most difficult cases within my experience have been those who have had their attention to the affected member kept up by too much local treatment after the joint inflammation had passed away.

Dr. L. Weber has seen some cases of muscular atrophy following joint disease, and remembers one in particular which may be of interest to the Society.

Mr. J. W., age thirty-two, merchant, of nervous temperament, but strong and active, made a tour through

Switzerland in the summer of 1870. Being a good pedestrian, he traveled mostly on foot, but after a severe Alpine tramp in the upper Engadine he was taken with synovitis of the right knee-joint. When the effusion had passed away the extensor muscle above the knee had wasted considerably; the patient was unable to walk, and reached New York with difficulty. On examination the joint was found to be in good order again, but the atrophy of extensor muscle was still very marked, and the patient, by the support of a cane, walked, but not without difficulty. A four weeks' course of faradization made no appreciable change, and although he was assured that he would regain the use of his limb completely in the course of time, he was not satisfied, but grew despondent, and finally left for Europe to consult Professor Erb. The latter told him the paralysis was not in his limb, but in his mind, that he should go about and exercise and live well and he would soon again regain the full use of his muscles. He followed the doctor's advice, and returned to New York early in the spring of 1880, in perfect health. As to the pathogenesis of the disorder, the doctor believes that the muscular paresis and atrophy in the case reported and in others of a like manner is of reflex origin, and that functional disturbances of motor centres in the brain, and not in the spine, is probably the cause of the trouble.

Of massage and its effect in such cases, as reported by the author of the paper, he has no personal experience, but has seen excellent results from its proper application in sub-acute joint diseases, muscular rheumatism, and bad sprains.

DR. E. C. WENDT said that the paper had brought out several points of interest, especially as regarded ætiology, symptoms, and the hopefulness of treatment. He was sorry to find, however, that the reader had nothing new to offer in explanation of the pathogenesis of these conditions. Admitting the correctness of Sappey's views concerning the richness in nerves of the articular and periarticular tissues, it certainly seems thoroughly puzzling why acute polyarticular rheumatism was not more frequently followed by just such accidents as Dr. Jacoby had described. Again those more chronic joint manifestations dependent upon the gouty diathesis, where profound structural alterations were frequently observed, only quite exceptionally led to atrophy, paralysis, and to other neurotic disturbances alluded to.

Upon these points he was sorry to find that the paper under discussion left us as much in the dark as we had been before.

With regard to massage, although his experience was limited, it was yet sufficient to fully convince him of its utility in certain cases. Of course, there is massage, and massage. But when properly and systematically applied it is useless to try now to dispute its beneficial action. The combined experience of a large number of competent men placed its usefulness beyond the pale of doubt.

DR. HEITZMAN said: When I was a student in Vienna a girl, twenty-five years of age, fell down stairs and acquired serous gonitis, after which she was paralyzed and confined to her bed for five years. She was sent to a water cure. A physician there urged her to walk in order to enable him to judge about the degree of the disease, but she began crying, and said she was unable. She went home in despair; her sister asked her to make at least an effort to walk. After considerable urging she got out of bed and walked. This illustrates that mental influence has much to do with these affections.

I would call the attention of Dr. Jacoby to an article by Dr. Micoladoni, published in 1871, in the *Wien. Med. Jahrbücher*. I have seen his specimens with the nerves brought out by the use of chloride of gold, and, from my observation, I am convinced that these terminal nerve fibres are not stable and unchangeable formations, but, on the contrary, new nerve fibres may form at any time of life from the living matter present in all tissues.

I am thoroughly convinced that nerves may disappear and appear, according to certain physiological necessities, certain physical conditions of the body, such as, for instance, results of exercise.

In an inflammation of a joint, the synovial and capsular wall being the seat of pathological changes, of the breaking down of the tissue, certain nerve fibres of the sensitive sphere will be within its range, and we should know that a certain number of them perish altogether.

Dr. Jacoby to-night did not give a theory of his own, but he quoted various authors. It certainly was the best plan for him to pursue, as so very little is known even in our day about nervous action.

We know that by the inflammatory destruction of a number of sensitive nerve fibres in the capsule of the joint at once three spheres are involved: the motor, for there is paresis or paralysis; the sensory, for there is pain; and the vaso-motor or trophic, for there is emaciation.

So far as my insight goes I am convinced that the living matter in a reticular arrangement produces the gray matter and all essential portions of nerves, including the axis-cylinder. This fact is thoroughly acknowledged by Professor Stricker at Vienna.

There may be loss of living matter of certain nerves, in consequence of inflammation, and loss of contractility, with impaired conduction towards the centre. We then have comparative rest in a limited portion of the spinal cord, or even the brain, for the reticulum of living matter is set at rest for a time, without there being a material change in the living matter of the gray substance and ganglionic elements.

If massage will reëstablish the activity of muscles we are prepared to understand that the field in the spinal cord before out of action may at once be brought in motion, and the motion communicated at once to the motor ganglia and all the sympathetic centres, which are situated along the spinal cord, as physiologists agree upon. The nervous action may for a certain time be impaired or dulled, because the reticulum of living matter is in comparative rest, lacking an impulse from without. So soon as such an impulse is carried to the resting portion, either by mental action, energetic will, or by mechanical shock, such as is done in massage, or in any other way, the contraction of the living reticulum is induced, and the normal condition reëstablished. Neither the assumption of centripetal neuritis nor the theory of reflex-action can explain the phenomena observed after the inflammation of articulation and their sometimes speedy cure.

DR. HENRY LING TAYLOR said: I can contribute a case showing the beneficial effect of the use of the body battery. A woman, under the care of Dr. J. West Roosevelt, at the Roosevelt Hospital Dispensary, of middle age and neurotic personal and family history,

presented, among other symptoms, that of prickling sensation down right arm and in right hand. There was no joint trouble. Dr. Roosevelt and myself regarded it as one of the neurotic disturbances incident to a person of her temperament. The body battery was tried for its psychical effect, and the woman returned in two days with the abnormal sensations gone. The symptoms had lasted a considerable time. The same treatment was applied to her hand without effect during the week she has since been under observation. I regard the result in this case as entirely due to mental influence.

Before concluding my remarks I wish to speak of an interesting class of cases alluded to by Dr. Gibney, the pseudarthroses. We have in these cases nearly or quite all the symptoms enumerated by Dr. Jacoby in his paper, atrophy, hyperæsthesia or anæsthesia, etc., following mental restraint, there being no affections of the joints. I regard the trouble as functional, and seated mainly in the brain, and not in the spinal cord as Dr. Gibney believes, if I understand him. Almost anything calculated to make a profound impression on the higher nerve centres will often prove curative in these cases. This is, in my opinion, one of the most important effects of massage.

I have in mind three cases of ankle trouble following sprains, seen three to five months after injury. The acute symptoms had subsided, but pain, tenderness, and such impaired function as to cause limping persisted. These patients had been treated with supports, etc., for several months. Physical examination showed no local trouble not readily explained by mental condition. There had been recovery from the sprain without a corresponding readjustment of the nerve centres to the new condition. The patients were perfectly and rapidly cured by purely psychical treatment. I do not doubt that massage often accomplishes the same result through its psychical effects in similar cases, but it is an empirical method as generally employed.

DR. GARRIGUES said: What little experience I have had with massage is in its favor, but that is almost nothing compared with that of Dr. Taylor. Nevertheless I have used massage for ten or twelve years. I became acquainted with it when quite new, and have found it most excellent for secondary conditions and for treatment to which Dr. Jacoby alludes.

DR. MORTON said a few words upon the subject of the continuous body battery and its use. The battery consists of a simple pair of elements. I well recollect a case in which I used this with good effect. A gentleman came to me with chronic arthritis. Associated with it was paralysis of the extensor group of muscles; the foot was dropped and the toe dragged. He said no form of electricity that he had tried had done him any good. I told him that I would give him a battery which he could wear all the time, which consisted of pieces of silver and zinc connected by copper wire. The zinc was shifted about upon different parts of the body; a constant current was kept up, which could be tested at any time with ordinary litmus paper. While under alkaline treatment the battery worked with better results, the excretions being saline.

This battery is also useful in the treatment of chronic ulcers; the granulations formed will be found much more healthy. It is also beneficial in chronic eczema. This much he would add to the practical part of the paper, since the main question after all was treatment.

DR. GIBNEY said that at times it is very difficult to determine whether the atrophy precedes or follows joint diseases. It is his opinion that it is more frequently the accompaniment of epiphyseal disease than joint disease proper, and he wished to emphasize the fact — for a fact it is according to his observations — that the majority of grave lesions about joints in childhood was epiphyseal, in other words, a chronic epiphysitis. Synovial disease he believes to be rare. If one examined a hip, for instance, said to be the subject of disease, marked atrophy is usually found in the thigh and calf muscles long before any pronounced joint symptoms are presented.

The atrophy, he further stated, is confined to the muscles and not to the bony tissue. For it is a rule that in chronic epiphysitis, about the knee for instance, the epiphysis is actually elongated. He, in common with many other orthopædists, has long since regarded acute atrophy as one of the most constant signs of chronic articular ostitis, and he believed the atrophy to be purely reflex, and not the result of disease or of the pressure from apparatus or bandages.

One argument brought against mechanical treatment, namely, that atrophy was produced, is fallacious. The clinical history of these bone lesions proves this conclusively.

He was not sure whether chronic synovitis induced atrophy, but he was very positive in stating that in acute synovitis atrophy was rather the exception than the rule.

A class of cases presented certain neuroses which were very valuable in excluding bone or joint disease. These are known as spinal pseudo-arthropthy, and known furthermore as neurosis of the joint, neuro-mimosis, hysterical joints, Brodie-joints, etc. The neuroses referred to were neuralgia, hyperæsthesia, anæsthesia, but rarely any atrophy. He believed that they had their origin in the spinal cord and the meninges, and the readiness with which they responded to spinal treatment confirmed him in his belief.

Furthermore, the neuralgia of chronic articular ostitis of the hip is well known, and the knee branch of the obturator is never affected early, and very often late in the disease, although this is denied by some writers, and especially a recent writer, Dr. Clippingdale.

In some of the most advanced cases of caries of the hip this obturator neuralgia is very distressing. Very frequently the sciatic nerve is involved, and in some cases narrated, especially one in a young lady with old disease at the hip, the sciatica was most distressing, and yielded very poorly to drugs and electricity.

The question of paralysis and degenerative nerve changes being sequences of chronic arthritis was one about which he did not feel fully convinced.

He referred to a case of chronic arthritis of the knee in an old woman who had paralysis of most of the muscles of the thigh and leg, and it was thought by some who saw the case that the paralysis was dependent on the joint lesions, but the proof was not by any means conclusive.

DR. JACOBY said: The first point to which I desire to reply is that brought forward by Dr. Taylor. He said that he believed these nervous changes, particularly the paralysis and atrophy, were produced by psychical or mental influence, and that they might be relieved by attention to this point. I am at considerable variance with him as regards the effect that mental in-

fluence has in the production of these disturbances. I for my part cannot understand how mental uneasiness can produce an atrophy, which is easily diagnosticated by the tape, of a certain muscle, and that in the short time of three days. But, as the doctor has promised us a paper upon this subject, perhaps that will succeed in convincing me.

As regards the opposition which the massage treatment has received, I expected it would receive more. Massage has, especially in the United States, been very much in the hands of non-professional men, and consequently has been greatly abused and misapplied. But I hardly think there can be any question as to its efficacy in suitable cases and when properly applied.

The theory advanced by Dr. Heitzman is very similar to that of Professor Charcot, who, as I mentioned in the paper, believes that certain parts of the cord are in a state of inertia or stupor.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

PREVENTION OF PUERPERAL INFECTION.

AT the December meeting of the Society, held Friday evening, the 21st, DR. H. J. GARRIGUES read a paper on the above subject. It was mainly devoted to an account of the manner in which puerperal septicæmia had been eradicated under his management from the wards of the Maternity Hospital on Blackwell's Island. This is in connection with Charity Hospital, to which all obstetric patients were transferred from Bellevue Hospital about the year 1875.

In this year the number of confinements was 515, and the deaths, fifteen, a mortality of 2.67. In 1876 there were 536 confinements and twenty deaths, a mortality of 3.73. In 1877 there were 480 confinements and thirty-two deaths a mortality, of 6.67. In 1878 there were 225 confinements and seven deaths, a mortality of 3.11. In 1879 there were 254 confinements and eleven deaths, a mortality of 4.40. In 1880 there were 149 confinements and eight deaths, a mortality of 5.37. In 1881 there were 382 confinements and nine deaths, a mortality of 2.31. In 1882 there were 439 confinements and fourteen deaths, a mortality of 3.25. While some of these deaths were attributable to other causes, the great majority of them were due directly to hospitalism. For a few years past separate pavilions had been used for the lying-in patients, but the mortality had still continued large.

In the first three months of 1883, when Dr. Garrigues was himself in charge of the wards, there had been 108 confinements and no less than eleven deaths. During the six months of his service, from October 1, 1882, to the end of March, 1883, 192 women were confined, and of these forty-six, or about one in four, were seriously sick. Thirty-nine of the number, or about one in five, suffered from inflammatory puerperal disease. On the 1st of October, 1883, he again came on duty, and found the condition of the hospital much the same — nine patients having died within the past month, and several of the women being still very ill. In the meanwhile bichloride of mercury had come into notice as an antiseptic, and he resolved to give it a full trial; but at the same time he thought it well to adopt other precautionary measures in addition.

In the first place: he divided the hospital into two departments: one for the well, and the other for the sick, with separate physicians, nurses, and instruments. He employed rapid alternation in the use of the wards, and each patient was allowed to remain eight days in the pavilion where she was confined, when she was removed to the convalescent ward. The doors between the wards were kept locked, all chinks were filled up, springs were placed on the doors of the water-closets, and solution of bichloride of mercury used freely everywhere. As soon as a ward was vacated it was fumigated; twenty pounds of sulphur being burned for this purpose in the larger wards, and fifteen pounds in the smaller. When it was again occupied every piece of furniture was washed with a solution of the bichloride of mercury (one to 1000), and fresh bedclothes and new straw for the beds were provided. Large demijohns of the solution were kept standing in all the wards, and for the hands of the physicians and attendants it was used undiluted, except in cold weather, when a small quantity of warm water was added to it. For use about the patient's person it was diluted one half, very hot water being employed for this purpose in cases of post-partum hæmorrhage.

When labor was coming on the patient was given an enema and bath at first, after which at least two quarts of the bichloride solution were injected into the vagina by means of a fountain syringe. There was a large glass vessel, with which was connected a long rubber tube, at whose extremity was a straight glass tube for the vagina. When it was necessary to use intra-uterine injections a curved glass tube was employed. In tedious labors the vaginal injections were made every three hours. At the beginning of labor the physician and nurse were both required to wash their hands thoroughly with soap and water by means of a large nail-brush, after which they were to allow their hands to remain in the bichloride solution for a minute or more. In case of more than one patient being taken in labor at the same time, the hands were to be treated in the same manner before passing from one patient to another. No other lubricant than the bichloride solution was employed, except in case of operation, when glycerine was used with the solution; glycerine itself being a good antiseptic. When the child's head appeared at the vulva it was covered with lint wet with the solution, and after the expulsion of its body the genitals were kept carefully covered. The placenta was expelled by Credé's method. Intra-uterine injections were resorted to only in cases where it had been necessary to introduce the hand or instruments into the cavity of the uterus. No portion of the placenta or membranes was ever allowed to remain in the uterus, as it was considered safer to introduce the whole hand into the uterus, if necessary, than to run the risk of hæmorrhage or septicæmia from this cause. The curved glass tube used for intra-uterine injections was fifteen inches in length, and had a large opening at the end, while there were eight smaller holes at the side. It differed from the Chamberlain tube in having the orifice at the extremity and a greater number of holes at the side, while its calibre (a quarter of an inch in diameter) was considerably smaller. On account of its small size it could be used at a comparatively late period, when the os uteri had become considerably contracted. The opening at the end permitted the stream from the syringe to impinge directly against the fundus, and by means of the numerous holes at the side,

which were all within a distance of four inches from the extremity, the walls of the uterine cavity were thoroughly washed with the antiseptic solution. When used directly after labor it was held in position by means of the fingers; but if at a later period, and there were any signs of inflammation present, a Cusco speculum was first introduced into the vagina. If there were any diphtheritic deposit (which had hitherto been found very likely to occur at the Maternity Hospital), it could be thus seen to advantage, and the tube could be introduced into the uterus through the speculum.

After every labor the vulva was covered with a piece of lint six by eight inches folded lengthwise, so as to make its width three inches, and over this was placed a piece of oiled muslin nine by four inches. Over this again was placed a large pad of oakum; the whole dressing being kept in position by means of a piece of muslin eighteen inches square, with all its sides folded over, so as to form a kind of boat, which was then pinned securely to the binder in front and behind. This dressing was put on with the same special care that would be used in dressing a wound after a capital operation, and it was changed four times in each twenty-four hours. Before making the change the nurse was always required to use the precautions in regard to her hands alluded to above. When this plan was pursued preventive injections were unnecessary, and thus one of the greatest dangers from infection was avoided. During the eight days that the patient was in the lying-in pavilion no visitors were permitted to see her, and this rule extended even to clergymen, unless the patient were seriously ill.

Carbolic acid was used only for instruments, the solution of bichloride of mercury corroding the metal, and also becoming weaker itself in consequence. In two or three instances the bichloride had produced slight eruptions upon the skin, but in no case had the drug been abandoned on this account, and in no case had it produced any general symptoms. Some of the nurses complained of sore hands caused by it at first, but the difficulty was quickly remedied by the use of glycerine. The lochia were kept entirely sweet by it, and the use of the drug was always continued as long as the patient remained in bed.

As to the results obtained by the plan of treatment thus described, from the 1st of October up to the present time there had been ninety-seven women confined, and not a single one had died. Six had been more or less sick, but only one had been seriously ill. This was a case of eclampsia. Three cases of metritis and two of perimetritis made up the six. In two only had there been any rise of temperature, although some of the labors had been severe, including two versions and one craniotomy. Formerly, on the other hand, there had been more or less rise of temperature in from one third to two thirds of all the cases of confinement. In short the pavilions were scarcely recognizable now by those who had previously been familiar with them. Instead of being filled with foul air the wards were pure and sweet, the physicians and nurses were no longer overworked and anxious, and the patients were bright and cheerful instead of despondent and foreboding.

Bichloride of mercury possessed several advantages over carbolic acid, among which were the facts that it was a much more efficient antiseptic, and that it was an excellent deodorizer while being free from odor itself. It also affected the hands much less unpleasantly than carbolic acid. It might be objected to the paper, Dr. Garrigues continued, that the time during which the plan of treatment described had been tried had been too short to prove anything. But the change in the condition of the patients and the wards had been so sudden and so remarkable that he thought it could be attributable to nothing but this, and he believed that the same results could be continued indefinitely if the same attention to detail was maintained. The great factors in the success, in addition to this careful attention to detail, were the use of the bichloride of mercury and the exclusion of air.

DR. MURRAY was the first speaker who took part in the discussion which followed the reading of the paper. The latter had been especially interesting to him, he said, because he had been Dr. Garrigues' immediate successor as visiting physician to the Maternity Hospital. During the three months of his service there had been ninety-six confinements with fourteen deaths. Four of the fatal cases, however, were not due to the results of labor, so that the mortality from hospitalism was eight out of the ninety-six. The form of puerperal fever which had prevailed was very similar to that which had been met with in Bellevue Hospital about ten years ago, and was frequently characterized by diphtheritis. Puerperal peritonitis was very seldom seen. The diphtheritic deposits would commence at the vulva and gradually extend up the vagina, but rarely into the interior of the uterus unless the case were protracted as long as two weeks, when this result was liable to occur. The symptoms were not very well marked at the commencement of the attack, and the pulse did not often run above 100 during the first few days. Afterwards it was very apt to be intermittent. With the appearance of the diphtheritic deposit typhoid symptoms usually became developed, and in some cases the patients sank into a semi-comatose condition. In a certain ward the women almost invariably had diphtheria, and notwithstanding that it was disinfected as perfectly as possible the same result was noticed afterwards when it was reoccupied. When Dr. Garrigues came on duty he had the advantage of a new ward, which had not been used for a year, and this he thought might have had something to do with the results shown. When the lying-in wards had been in Charity Hospital it was always noticed that when a new ward was taken possession of there was a marked improvement for about a week. Still he questioned very much whether the immunity from mortality was due to this cause alone, and was disposed to give Dr. Garrigues full credit for the efficient system for the prevention of infection which he had inaugurated. In private practice he thought all this minute attention to detail was unnecessary, though the main features of the treatment might be carried out with advantage. Before concluding, Dr. Murray spoke of the inefficiency of carbolic acid in the treatment of puerperal diphtheria. As soon as the slight slough which was caused by its application had come away he had often noticed the diphtheritic deposit to spread to all the points which the acid had touched, and he had seen the patches appear just the same after patients had been actually cauterized with it.

DR. WYLIE referred to a paper which he had read before the County Society about six months ago, and said that he commenced to use antiseptics in midwifery when an interne of Bellevue Hospital in the year

1871. He attended thirty-six cases of confinement while serving in the lying-in department, and there was not a single case of puerperal fever among them. The only death that occurred was due to convulsions. He had observed the same measures in his private practice ever since, and had never had but one case in which there was a rise of temperature during the first few days after delivery. When there had been any febrile movement it had occurred after the eighth day, and had been due to mastitis. He was in the habit of washing out the vagina with a solution of carbolic acid of the strength of one to fifty, or more often of one to thirty, and also of carbolizing the bed linen; while he always insisted on having two sets of blankets and at least thirty-six napkins for the use of the patient. He would now try bichloride of mercury instead of the carbolic acid. In conclusion, he said that he could not agree with Dr. Murray in regard to there not being the same necessity for taking every precaution against the occurrence of infection in private practice. A physician might have the most uninterrupted success for a long time in his obstetric practice, and yet septicæmia at last make its appearance.

DR. GILLETTE stated that he had been connected with the maternity service on Blackwell's Island for twelve years, and that he had sole charge of the lying-in wards of Charity Hospital when the obstetric patients were transferred from Bellevue Hospital. For years puerperal fever had been epidemic at Bellevue, and all efforts to break it up had proved futile. At last the mortality became so great that it was determined to discontinue the lying-in service there entirely, and, accordingly, forty women were removed to Charity Hospital. They were all saturated with the influences that had prevailed at Bellevue, but under the counteracting influence of extraordinary cleanliness only one case of puerperal fever occurred among them. Nothing was known of Listerism then, and no special antiseptic treatment was employed except carbolic acid baths. He thought there could be no question of the importance of all the suggestions which Dr. Garrigues had made, but there might be some discussion as to the methods which he proposed. The latest germicide to attract attention had been the bichloride of mercury, and so at the present time everybody was expected to bow down to it, although he was not as yet convinced that it was of more value than some other antiseptics. In regard to Dr. Garrigues' vulvar dressing, he could see theoretically how it might do good, but practically he did not believe it was of any service, for the simple reason that it could not be kept in absolute contact with the parts to which it was applied, and, consequently, there must be plenty of room for the entrance of any germs that might be in the air. The great secret of the success which had been reported he believed to be perfect cleanliness, and he was also disposed, like Dr. Murray, to attribute it in part, at least, to the fact that Dr. Garrigues had commenced in a new institution.

DR. ALEXANDER T. HUNTER made some remarks, in the course of which he spoke of the superior advantages of the tube devised by Dr. George H. Lyman, of Boston, in cases where it was desirable to resort to intra-uterine injections; after which DR. BARUCH said that he was glad to hear the author of the paper speak against the use of prophylactic antiseptic injections after normal labor. For himself, he could only condemn them in the most unqualified manner. During the last twenty years he had attended about nine hundred cases of confinement, including every variety of complication, and had had but one death which was preceded by febrile symptoms. Even this one was not due to any septic influence. It was only since Dr. Wiley had read the paper before this Society to which reference had been made that he had tried the use of prophylactic vaginal injections, and he was sorry to say that his experience with them had not been at all favorable. In no less than six cases, in all of which the women were faithfully syringed, he had seen fever which was undoubtedly of septic character occurring in from five to eight days after delivery. He then went on to say that there was a distinct reaction against the use of such injections now taking place in Germany, and that they seemed to him to be objectionable on the following grounds: (1.) He believed that the lying-in patient ought to be kept as quiet as possible, and the injections interfered with this. (2.) It was impossible to give them without subjecting the patient to a certain amount of pain and exposure. (3.) Very few nurses know how to give injections properly. (4.) They were liable to displace clots and thus open avenues for auto-infection. (5.) They might also loosen adhesions. In his opinion simple cleanliness before, during, and after labor was all that was necessary.

DRS. F. V. WHITE, J. P. GARRISH, and J. C. PETERS then spoke, and DR. GARRIGUES brought the discussion to a close. In the course of his remarks he said that while one of the wards was new the others had been in constant use, and had previously contained many fever cases. There were three wards occupied by the lying-in patients in rapid alternation. The vulvar dressing had been devised with special reference to the shape and size of the parts to be covered by it, and he thought that if applied with proper skill it was efficient in excluding septic germs.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, M. D., RECORDER.

THURSDAY evening, December 13, 1883. DR. J. H. MUSSER in the chair.

ENORMOUS HYPERTROPHY OF THE HEART (WEIGHING FORTY-EIGHT OUNCES).

CHARLES W. DULLES, M. D., reported the case.

The patient from whom this specimen was obtained was a young man, eighteen years of age, who came under my care in February, 1882, in an attack of muscular rheumatism, principally affecting the shoulders. I found at that time great oppression of breathing, a heart dilated and hypertrophied, with a harsh, strong, mitral systolic and presystolic murmur. His urine contained bile coloring matter, great excess of urates, great lack of chlorides and phosphates, and no albumen or sugar. In the sediments only amorphous urates were found. The treatment employed included the administration of infusion of digitalis, with iron and strychnia. At one time, believing it might benefit the violence I attributed to the real hypertrophy, I gave him veratrum viride. But it did no good. I did, however, get apparently good and prompt relief from some of the symptoms by the use of iodide of potash, in twenty-grain doses, thrice daily. After using this for a week, I noted in my case-book: "Sleeps well;

eats well; feels well; cough very slight; urine clear; pulse better; *cannot hear the old murmur* (perhaps barely); both heart sounds audible and pretty clear; action of heart fair." (It had been very tumultuous.) After six weeks of doing well the patient had a new attack of uneasy stomach, dyspnœa, and more or less cyanosis. On the night of May 10th he had a frightful attack of dyspnœa; I gave him one fifth grain of muriate of pilocarpine hypodermically (in the left arm), under the influence of which he sweated, but had no salivation. The next day he had a large œdematous swelling of the left side of his neck, below the jaw, and reaching to the middle line in front. This increased up to the evening, and gradually subsided in three days.

About this time fluid began to accumulate in the abdomen and thorax, and there was, of course, œdema of the feet and legs. There was also heard now a most beautiful water-hammer pulse over the femoral arteries below Poupart's ligament. The pulse here was intermittent and had a reduplicated sound like this . —, . —, . —, . —, etc.

Three weeks later another severe attack occurred, and again about three weeks after this. There were now in his urine considerable albumen and hyaline tube casts. When his attack came on, which was at night, I gave him one third grain of the muriate of pilocarpine hypodermically, which produced free sweating and brought out about two fluid ounces of saliva. His pulse came down from 140 to 100 in half an hour. But the dyspnœa abated only temporarily; the restlessness continued; the cyanosis increased; the respiration varied from 35 to 60 per minute; then his bowels moved involuntarily, his lungs seemed to fill up with œdema, and he died asphyxiated.

The autopsy was made the next day, with the assistance of Dr. Formad and Dr. J. H. Musser. The points of interest were as follows: General œdema of feet and legs; the face and neck and chest covered with purpura-like spots and patches. The abdomen contained about two quarts of clear serum; each pleural cavity nearly as much. The lungs were normal but small, and occupied the upper part of the chest. They were quite œdematous. The liver was slightly fatty, the spleen was of normal size, but very hard and tough. The kidneys were large, congenitally lobulated, and in a state of cyanotic hypertrophy.

The heart was enormously hypertrophied, weighing, when all the adherent parts were removed, forty-eight ounces. The pericardium was so uniformly attached to it that it could not be removed, and there was absolutely no pericardial cavity. The right ventricle contained about six ounces of soft post-mortem clot. The left side contained about two ounces similar. After the heart had been opened and well washed it weighed forty ounces. All the valves and blood-vessels were healthy. The tricuspid and aortic valves were quite competent. The mitral orifice was enormous — measuring two and a half inches across. Every part of the heart was hypertrophied, and all to about the same degree. The whole organ, which I here show, was about the size of that of a bullock.

The points of interest in this case — aside from the curiousness of the specimen — seem to me to be the comparative immunity of the kidneys; the absence of signs of adherent pericardium; the benefit derived from the use of iodide of potash; the temporary disappearance of the very strong mitral systolic and pre-systolic murmur; and the parotid swelling, following the hypodermic injection of pilocarpine in the arm of the same side. Dr. J. H. Musser remembered distinctly the case both before and after death. He had marked out on the chest the dimension of the heart and made it out as enormous, extending especially to the right. Furthermore, he thought that there was a double mitral murmur. The only apparent cause for the hypertrophy was the adherent pericardium. He would like to know what Dr. Henry thought of the correctness of this explanation.

DR. F. P. HENRY said that the heart presented was remarkable not only for its enormous size but also for the absence of the usual causes of cardiac hypertrophy, there being neither valvular disease nor obstruction in any part of the circulation. During his student days he had seen some very large hearts in the collection which Prof. Alonzo Clarke was accustomed to show to his class, but would not trust his memory so far as to affirm that any one of them was as large as the one just shown.

DR. MACCONNELL had seen a case in a member of the Modjeska troupe where post-mortem examination showed an enormously hypertrophied heart with adherent pericardium and markedly granular kidneys. In this case the hypertrophy was clearly due to the kidney trouble.

DR. FORMAD thought that Dr. Dulles' case was unique as to size. Dr. Robinson, of New York, had recently reported a case of hypertrophied heart, weighing fifty-six ounces, but Dr. Dulles' specimen was weighed after removal of clots, etc.

DR. MUSSER asked whether other members of his patient's family had not hypertrophied hearts without valvular lesions. If such was the case, taking into consideration the age of the patient, it would be well to consider the probability of the hypertrophy being in part secondary to the pericardial adhesions, in part idiopathic in origin.

DR. DULLES said that there was a tendency to hypertrophy of the heart in one sister, and that the murmur at times was double.

(To be continued.)

— In the duty of the medical journalist to welcome the coming, speed the parting guest, it falls to our part to chronicle the demise of the *Archives of Laryngology*, which we do with regret, and to announce the appearance of *The Analectic*, a new periodical designed to select and analyze the essential items of medical progress from the publications of this and foreign countries.

— *The Archives of Medicine* has also suspended publication after a satisfactory existence of five years. It is to be regretted that this journal, which has filled a valuable place in supplying purely original material to its readers, is obliged by a combination of extraneous circumstances to retire from the field.

— The *Illustrite Monatsschrift der ärztlichen Polytechnik* and the *Centralblatt der orthopädeschen Chirurgie* will hereafter appear as one publication.

— Mr. P. T. Barnum has been making a will, disposing, it is said, of some $10,000,000, and has called a number of physicians to give evidence of his mental soundness at the time of the execution of the instrument.

Medical and Surgical Journal.

THURSDAY, JANUARY 3, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

ANNUS MEDICUS INCIPIENS.

As last week brought the annual duty of summing up the medical events and results of the year which has just left us and contributing thus, it is to be hoped, to his euthanasia, so this week brings the no less periodical pleasure of wishing to our friends all they desire of good during the new year upon which we are all just entering. Hope, that best though delusive companion, is again starting trippingly on the journey as though she had never misled and even abandoned those who confided in her guidance; may vigor and perseverance be added to the company, enabling it to attack new questions and bring old ones to happy conclusions. There are plenty of dragons still to be slain, captives to be rescued, and rough places to be made smooth.

Were not the spirit of prophecy such a dangerous one to imprison in print, we might outline the present medical year as we have the past, at least in so far as the one inherits from the other.

Contributions will be made to the facts upon which the germ theory of disease is based, and the significance and scope of that theory will be somewhat more clearly defined. The Collective Investigation of Disease will be carried forward in England, on the Continent, perhaps in this country, and the methods by which the greatest advantage may be drawn from it will be gradually evolved. Both our own continent and that of Europe will be somewhat occupied next summer in guarding against any dangers from the relics of this year's epidemics of yellow fever and cholera, the present course of events in Egypt rendering a revival of cholera by no means improbable. Congress will discuss the value and functions of a national board of health, and, we will predict, while acknowledging the desirability of having a national board with a tolerably broad basis of representation, will leave the administration of maritime quarantine matters to the Treasury Department, assigning to a board of health the duty of pursuing and directing investigations of abstract hygienic problems which confront us as a nation and as individuals, and of making sanitary surveys. The possibilities and limitations of quarantine will probably in any case attract much discussion abroad as well as at home.

Congress will in its wisdom make an appropriation to provide the Army Medical Museum and the Medical Library of the Surgeon-General's office at Washington with a fire-proof building.

The medical societies of the different States will not allow the *Index Medicus* to become extinct.

Massachusetts will restore, or will prepare to restore, her Board of Health to its existence as a separate entity, and will simplify the organization of the complex body now known as the Board of Health, Lunacy, and Charity.

There will be a sharp contest in her courts and Legislature over the enforcement of the law to prevent the adulteration of food and drugs, in which the rights of the public to be protected will eventually prevail over the desire of the manufacturers to be rich.

The system of medical examiners obtaining in this State will receive favorable consideration in other States, warning the old coroners to withdraw.

In the domain of therapeutics the synthetic process in the chemical laboratory may have surprises in store for us.

We risk less in averring that medicine will again be robbed of some good followers, whose places will be taken by others now less known.

In the above short paragraphs sufficient prophetic hostages have been given to fortune. Should some of them fail to be redeemed we shall shelter ourselves behind the wish, which perhaps was father to the thought; and laying aside the prophet's mantle we revert in closing to the agreeable and certainly safer function of wishing all who journey with us a happy and prosperous new year!

LITERATURE IN MEDICINE.

THE profession of medicine is making progress by means of the constant study done in the laboratory, at the bedside and in the library, by a series of trained students and observers.

Laboratory work has accomplished so much for the good of the profession, and has assumed such importance in the eyes of educators, that there is danger lest work of other descriptions, not less important, should be under-estimated. "Original scientific work" is in the present day too apt to be considered the only claim to distinction, and that phrase is held to mean, almost exclusively, work in the physiological or chemical laboratory, and clinical and literary labors are apt to be under-valued if not despised. The propriety of such an attitude toward these latter methods of study is discussed in an address on the Place of Literature in Medicine by Dr. C. J. Cullingworth, Lecturer on Medical Jurisprudence in Owens College, Manchester, England, before a students' society of that institution. He intimates that the term "original" is not always appropriate as applied to such laboratory work, which consists in the carrying out of a series of observations and experiments under the direction of a teacher to whom is not only due the suggestion of a subject for inquiry, but also the laying down of the lines of the inquiry itself. Unless originality of thought on the part of

the worker himself is involved the phrase is open to objection. In the gentleman's opinion, while he is far from detracting from the value of researches which lead to even the slightest addition to exact knowledge, there is nothing in laboratory work itself as distinguished from clinical or literary work which gives it an exclusive right to be regarded as original and scientific.

Literary work may be as deserving of the designation *scientific* as any other, and of immense value to practical medicine. Not every man who contributes an article to a medical journal can be described as literary. Unfortunately our journals too often contain limited personal experience and hasty generalizations recorded with complete ignorance of what has previously been written on the same subject, but it is one of the functions of the literary worker to rescue from oblivion the valuable facts scattered through the voluminous literature of medicine, and render them by comparison and collation useful to the profession. To bring together unusual cases, to elucidate a symptomatology from the collected histories, to put the practitioner on the watch in regard to such cases, and mark out lines of future inquiry which shall enable the next man who meets with a similar case to complete the story, what more profitable work can be found for the student?

As a sample of such *scientific* literary work, the earlier editions of Bumstead's Venereal Diseases may be mentioned. The later editions were enriched more largely by his own observations, and deserve recognition for combined literary and clinical work, but of the first edition the author claimed only that he had collected into one volume, and thus rendered more accessible to the American reader, the investigations and results scattered through the pages of medical periodical literature in our own and foreign languages.

This is an extreme example of such work; it is ordinarily done on smaller subjects, and is peculiarly fitted to men at the very commencement of their career, when their experience at the bedside is as yet too small to justify them in drawing materials from it alone for contributions to medical literature.

As an assistant to such work Dr. Cullingworth speaks of the *Index Medicus*: —

"It is a remarkable example of American enterprise, and one can but feel deep regret that it has hitherto failed to obtain sufficient support to repay the cost of its publication. Recognizing the great loss it would be to medicine for such a publication to be discontinued, several of the medical societies in the United States have subscribed to a guarantee fund, from which the publisher, who for the first two or three years bore the entire risk, is for a short time to be recouped for any loss he may sustain by its continuance. I am glad to say that of all the towns in Great Britain, Manchester is the one which furnishes the longest list of subscribers in support of this enterprise."

In attempting to collate the facts recorded by others one constantly finds the most important facts omitted and generalizations added in abundance. "The great obstacle to the development of a science of medicine is the difficulty in ascertaining what cases are sufficiently similar to be comparable, which difficulty is in its turn largely due to insufficient and erroneous records of the phenomena observed. . . . Very, very few are the men who can, by and for themselves, see and describe the things that are before them. . . . We had to wait long before the man came who could see the difference between measles and scarlatina, and still longer for the one who could distinguish between typhus and typhoid." We fear many cases are lost to the world which would prove not only of paramount interest but of great value to the profession, through the modesty of men who hesitate to publish cases because of their inability to explain every symptom which has appeared. "The report of a case," says Dr. Billings, whom we have just quoted above, "in which every symptom observed and the effect of every remedy given is fully accounted for, and in which no residual unexplained phenomena appear, is usually suspicious, for it implies either superficial observation or suppression or distortion of some of the facts."

No one need despair, then, that laboratory experiment is not to their taste. The literary doctor has his uses as well as the more strictly scientific, if only he will learn to use his literary ability for the service of his profession. Diversity in preliminary medical education is certainly an advantage to the profession, as furnishing a class of men who are able to profit by and make profitable to all the work of the observer and the experimenter.

PERMISSIVE EUTHANASIA.

Among the queries made by the Poet at the Breakfast Table of the man of the fortieth century A. D. is one whether the euthanasia has become a recognized branch of medical science. The Journal has already noticed the assumption on the part of certain practitioners that a monstrosity should be put out of the way as soon as possible after birth, which proposal, though not (we are happy to say) generally "recognized," is in its measure a present realization of what the Poet thought a possible development of two millenniums. We now find in an exchange the frank confession of a physician on the frontier that he believes in and has acted on this principle in the treatment of an adult. The patient was a pauper, and was suffering from a serpiginous phagedæna which had destroyed the external genitals, and had spread into a large ulcer extending from the perinæum to the hypogastrium. He was alone, covered with filth and flies, dependent on the tender mercies of county commissioners, and apparently too weak to be moved to an almshouse. The reporter considered it his "duty as a conscientious physician," and in fulfillment of the "golden rule," to administer sol. Magendie ʒi., which succeeded in fulfilling the indication for euthanasia, *cito tuto et jucunde*.

Whatever the fortieth century may have in store for us, we believe that the profession is not quite pre-

pared for this teaching at present. We are not as yet ready to see the functions of Atropos added to those of Asklepios.* But, on the other hand, though we would never become destroyers of life, we suspect few physicians have escaped the suggestion in a hopeless case of protracted suffering to adopt the policy of *laisser aller*, to stand aside passively and give over any further attempt to prolong a life which has become a torment to its owner. For instance, a woman has malignant disease advanced far beyond the chance of operative interference. The odor is horrible, and not to be suppressed. Pain is intense. The stomach refuses its work. Fatal hæmorrhage momentarily threatens. For weeks the physician has combatted death at each of these points; has taxed to the utmost the art of the cook to appease the recalcitrant stomach; has crowded in food and stimulant by every channel, and all for what? to exhaust the strength and perhaps imperil the lives of the remainder of the household: to keep in their home a body which is repulsive to every sense and a mind which is no longer that of their friend, but which is overclouded if not maniacal; or, if the sufferer retains consciousness, to meet her bitter reproaches for prolonging her misery. Shall not a man under such circumstances give up the fight, take off the spur of the stimulant, and let exhausted nature sink to rest?

One of the most ghastly of Poe's tales is of a man whose soul was by some mesmeric influence kept in his body for weeks after the body was dead and decaying. The agony with which with swollen tongue and rattling voice he implores to be set free is vividly depicted, until at last the spell is taken off, and as the soul escapes the corpse collapses, "a loathsome, almost liquid mass of detestable putrescence." Even this emphatic language is hardly an exaggeration when applied to the bodies in which the physician sometimes fancies himself called upon to enchain for a little longer the struggling life. If the open upbraiding of the patient is wanting, the unspoken desire is often present to be delivered from this body of death. A garrison is brought face to face with inevitable surrender. The friendly general has not troops or supplies enough to relieve the besieged, and is perfectly aware of it. Shall he send in the pittance that can be introduced merely to prolong the garrison's suffering a few more days, when the surrender must inevitably be made?

Perhaps logically it is difficult to justify a passive more than an active attempt at euthanasia; but certainly it is much less abhorrent to our feelings. To surrender to superior forces is not the same thing as to lead an attack of the enemy upon one's own friends. May there not come a time when it is a duty in the interest of the survivors to stop a fight which is only prolonging a useless and hopeless struggle?

— The city government of Paris tested, during the month of November, the French wines brought into the market. Out of 1518 samples examined only sixty-five were found absolutely free from injurious adulterations.

THE DECISION IN REGARD TO THE PRIZE FOR ESSAYS ON MALIGNANT DISEASE, ITS CURE, AND THE METHODS OF INVESTIGATION TO BE FOLLOWED.

IN our advertising columns will be found the decision of the judges concerning essays on the subject of Cancer presented in accordance with an announcement made in March, 1882. The result is to be regretted. The subject, it must be admitted, was a difficult one, but so much the more surprising is the lack of serious and painstaking endeavor noticeable in the majority of the essays offered. We must confess, too, to some surprise at the absence of other than writers in the English language, for the announcement concerning the prize offer was extensively published in France, Germany, and Austria, permission being given to employ the French or the German as well as the English language.

The amount of the prize offered — one thousand dollars — was certainly sufficiently large to act as a spur to scientific zeal, and to have called forth a keener competition than is represented by the six essays which it is announced were received. Nineteen or twenty months was, moreover, time enough for serious preparation. There is no doubt that the benevolent proposer of the prize is not the least disappointed of those concerned.

MEDICAL NOTES.

— The Naval Advisory Commission has recommended the sale of the whole or the larger part of the Naval Hospital grounds at Chelsea, Mass. The cause is that the grounds are unnecessarily large, that they form an obstacle to public travel, and that they are too valuable to be kept longer from the market.

— A story illustrating the nutritiousness of the milk of the cocoa-nut is found in a daily contemporary. It seems that a vessel left San Francisco with four hundred passengers for Sydney, and, in consequence of running short of stores, put in at Samoa, where a large quantity of cocoa-nuts were obtained. The weather became so severe that the remainder of the passage consumed eight days, so that men, women, and children were reduced entirely to a cocoa-nut diet, and were obliged to be contented at last with but one per diem for each adult. "Notwithstanding this diet," says the report, "not a life was lost, and not a single case of sickness occurred, all the passengers landing in a healthy and well-nourished condition."

— The attorney-general of New York has begun suit at New York against the Eclectic Medical College of that city to annul its charter and dissolve the corporation. The attorney-general charges that the college has violated the provisions of its charter by issuing its diplomas in blank to enable persons not properly qualified to insert their names and illegally practice medicine.

— Dr. Robert T. Davis, member of Congress from Fall River, has been appointed on the Committee for Public Health. Dr. Davis's long experience on the

Massachusetts Board of Health should make him a valuable member of that committee.

— Frank Pere Lawrence, a member of the second class at the Harvard Medical School, died lately of pneumonia at the Massachusetts General Hospital, after an illness of about eleven days. Mr. Lawrence was an earnest student, and was highly esteemed by his classmates.

— Of Dr. Murray, who has lately been appointed Surgeon-General of the Army, the following incident is related: In 1850 General Sherman, then a young lieutenant, was stationed at Monterey. Returning thither on one occasion from a visit to San Francisco, he was attracted by the continuous crying of a child at a ranche on the road. He inquired the cause, and learned that the mother and her friends had done all they could for it, but as they were too poor to buy medicines or send for a doctor they had given up all hope and sat waiting for the poor little creature to die. As he was traveling under orders he had to push ahead with all rapidity, but on his arrival at the fort he related the incident with a great deal of animation and some pathos in the mess-room. Dr. Murray, then a young assistant surgeon, listened, with his heart in his eyes, and with the ardor of youth volunteered his services. He was given permission to go, and, hastily preparing for the journey, he rode *seventy miles* on his charitable mission. He was rewarded by the recovery of his patient, and the pleasure of reporting at the garrison the good news of his successful and unselfish enterprise.

Correspondence.

THE CLINICAL EXAMINATION OF DIABETIC URINE BY DUHOMME'S TEST.

MR. EDITOR, — There is no doubt that the quantitative method for dosage of diabetic urine, originated by Duhomme, and described by Dujardin-Beaumetz in a lecture published in this journal, November 15th, vol. cix., is the most expeditious and most handy yet known. Without claiming much experience in testing by this method, having had occasion to apply Duhomme's process to the examination of only two samples (from different patients) of saccharine urine, I am asked by several correspondents to clear up for them certain difficulties connected with the practical application of this test by physicians in this country. And first there is the disadvantage of not having the neat little apparatus of Limousin with the dropping tubes and all the other appurtenances. The most essential part of the apparatus is the graduated dropping tube (*compte-gouttes*), graduated at one cubic centimetre for urine, two cubic centimetres for Fehling's solution. These require to be very delicate, and easy of management. Those made recently by Codman and Shurtleff are a little clumsy in comparison with the "compte-gouttes" of Limousin. It is difficult with those of Boston manufacture to make the drops uniform or prevent the admission of air. I have lately obtained from Paris the apparatus of Limousin, and find the dropping tubes all that could be desired. I have no doubt that Codman and Shurtleff will be able in the future (with the samples before them) to furnish *facsimiles* of the French dropping tubes; with a little practice, however, one can obtain correct results with the tubes which this firm has already made.

With regard to the strength of Fehling's solution, this seems to be a matter of some importance. It should be of standard strength, *so that two cubic centimetres shall be exactly reduced by one centigramme of diabetic sugar*. I had a preparation made according to the formula given by Beaumetz in the November 15th lecture, except that for the neutral tartrate of potassa I substituted the tartrate of soda and potash (Rochelle salt). I find no difference between this solution and that of Limousin, which accompanied the saccharimetric apparatus.

As for the solution of soda, I do not think it makes any difference whether, in using Duhomme's process, you dilute the liquor Fehling (two centigrammes) with the solution of the French Codex or with the *liquor sodæ* of the United States Pharmacopœia. The main thing is to dilute the Fehling's solution with an equal quantity of an alkaline liquid. At the same time the preparation used on the Continent, a sample of which came with the Limousin package, is of specific gravity 1.14.

In a diabetic patient whom I am now attending, the proportion of glucose excreted in the urine continues almost a constant quantity. It takes just ten drops to redden the cupro-sodic solution. There are eighteen drops in each cubic centimetre. Referring now to Duhomme's table,[1] we find that there are eighteen grammes of sugar in each litre. This patient is now voiding sixty-four ounces or about two litres a day, hence is excreting rather more than an ounce of glucose.

The paper of Duhomme explaining the *rationale* of his process is too lengthy to be reproduced here. Suffice it to say that the method has been wrought out by patient and painstaking experimentation, and may be relied upon as accurate.

Yours truly, E. P. HURD, M. D.

NEWBURYPORT, *December* 24, 1883.

NOTE FROM DR. WEIR MITCHELL.

AT Dr. Mitchell's request we insert the following communication to the editor of *The Medical News*: —

SIR, — Will you kindly publish the following statement, made necessary because of my receiving letters from England and this country calling my attention to the liberty taken with my name.

Dr. H. H. Kane, of New York, has made use of my name in an advertisement of a secret means of treating the opium habit, and afterwards, in a pamphlet labeled De Quincy Opium Home Cure, printed fac-similes of letters received by him years ago from a number of physicians, and among them a letter of mine. In obedience to a protest on my part Dr. Kane has removed my name from his advertisement, and my letter from his pamphlet.

Yours truly, S. WEIR MITCHELL, M. D.

December 22, 1883.

[1] Vide JOURNAL, November 15th. It should be mentioned in this connection that the quantitative analytical process of the Harvard Medical School embodies the essential principle of the Duhomme method.

Miscellany.

REFUSION IN CARBONIC OXIDE POISONING.

DR. WILLIAM S. HALSTED discusses in the *New York Medical Journal* (December 8th) this method of treating cases when death is imminent from inhalation of carbonic oxide or illuminating gas. The practice consists in removing a quantity of the vitiated blood, and after defibrinating and oxidizing it restoring it to the body of the patient. He quotes a few authors who have mentioned this method of treating collapse from exsanguination, as, for instance, Volkmann, who suggested the feasibility of utilizing the blood which unavoidably was lost in an exarticulation of the hip. In carbonic-oxide poisoning refusion involves an additional factor, namely, the oxygenation of the poisoned blood employed; and is, therefore, an infusion of the purified, defibrinated, for the poisoned, entire blood of the individual.

Two cases are given at some length where refusion was practiced on individuals deeply poisoned by illuminating gas. In the first there was coma which had resisted previous treatment. Respirations were very superficial. The superficial reflexes feeble or absent; the deep ones not to be tested on account of rigidity of the limbs. The right radial artery was exposed above the wrist for about one inch, and two ligatures passed under it. This was at 10.50 A. M. The report says: —

"A canula introduced centripetally into the artery was held in place by one ligature; the other was used to occlude the vessel peripherally. Through the canula 512 cc. of blood were withdrawn, defibrinated, strained, and kept at a temperature of about 37.5° C. in a transfusion apparatus. 11.20 A. M.: temperature 35.4° C. (95.8° F.); pulse 22; respiration 22, full and dyspnœic. Superficial reflexes well pronounced. Eyes closed, but patient can be made to open them. Rigidity of limbs has in great measure disappeared. 11.32 A. M., 288 cc. of defibrinated blood, all that could be obtained from the 512 cc., were refunded through the canula in the artery toward the heart — centripetal arterial infusion. At 11.45 the injection was completed. Temperature 36.6° C. (98° F.); pulse 104; respirations 28, deep and labored. Superficial reflexes possibly exaggerated. The usual post-transfusion rigors lasted for half an hour. 12.35 P. M.: 300 cc. withdrawn, as before, through the canula, defibrinated and mixed with 128 cc. of defibrinated blood taken from another patient. One P. M.: temperature 38.2° C. (100.8° F.); pulse 128; respiration 28. 1.05 P. M.: patient's pallor most striking; 192 cc. of the mixed blood infused. The color returned rapidly to his face when from 80 to 100 cc. had been injected, the change from a deathly white to a healthy red taking place in a few seconds. 1.13: temperature, 39.1° C.; pulse 120; respiration 40. 2.30: temperature 39.4° C.; pulse 140: respiration 40. 5.20: temperature 37.8° C.; pulse 116; respiration 20.

"Patient has been gradually returning to consciousness since the first venesection, and now attempts to get out of bed."

The next day the urine was voided voluntarily, the patient ate well, and desired to go home, which he did fifty hours after admission to the hospital. No ill effects remained.

In another similar case the patient, a young girl, was growing gradually worse, despite all ordinary treatment, and ultimately her condition became, in the opinion of her attendant, hopeless. Then 204 cc. of blood were drawn from the left basilic vein, whereupon the condition improved marvelously, — the respirations becoming full, the pulse less frequent and stronger, the rigidity disappearing, and the reflexes returning. Here an attempt to refund blood to the system failed on account of imperfection in the apparatus, so that only 30 cc. were introduced. The fact that the improvement was coincident with the venesection and that there was really scarcely any refusion, renders it doubtful whether in the first case a similarly fortunate result would not have followed simple blood-letting. The good effects of venesection in such cases have been established by observation as well as by experiment on animals. Why then, it may be asked, transfuse if venesection accomplishes so much? It for no other reason, says the author, to allow of repeated venesection. The poisoned individual should be bled freely, unless there be decided contra-indications, even after, to all appearances, out of danger, in the hope of diminishing the risk of pernicious after-effects.

Although bleeding of itself will probably suffice to save life in almost all cases which occur in practice, it has been demonstrated by Kühne that animals, poisoned beyond hope of rescue by venesection, can be saved by transfusion. In one of his experiments, where respiration had been suspended seven minutes, he was still able to restore life to the animal by the infusion of defibrinated blood.

The theory of a substitution of corpuscles capable of carrying oxygen for those so vitiated as not to be capable of performing this function, though an attractive one, is negatived by the fact that saline injections are as efficacious as whole or defibrinated blood.

As to the various means of introducing blood, centrifugal venous infusion is at once rejected. So is centrifugal arterial injection in view of cases of gangrene so caused, and of rupture of capillaries due to the force necessary to overcome the vascular spasm. Of the two remaining possibilities the centripetal arterial is to be preferred to the venous because the blood by the former method courses more slowly and uniformly to the heart; because the minutest air-vesicle is retained in the capillaries; and because the danger of phlebitis is avoided. Moreover, arterial blood is thus most directly dispatched to the nerve-centres, in consequence of which the venous blood there contained is propelled onward into the veins, and the filling of the arterial system rejuvenates the feeble circulation by creating a considerable difference in pressure between the arterial and venous systems. The practical results of the author confirm those theoretical advantages of centripetal arterial infusion.

PARACENTESIS OF THE PERICARDIUM.

DR. J. W. MACDONALD reported to the Canada Medical Association (*British Medical Journal*, October 27, 1883) a case of pericarditis with effusion attendant upon acute rheumatism, in which he performed paracentesis. Thirty-two ounces of fluid were withdrawn, greatly to the patient's relief. A partial re-accumulation of the fluid was met by elaterium and counter irritation, and the patient subsequently did well.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 22, 1883.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				The Principal Infectious Diseases.	Consumption.	Typhoid Fever.	Diphtheria and Croup.	Scarlet Fever.

Deaths reported 2524 (no reports from Cincinnati, District of Columbia, and Buffalo): under five years of age, 852: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 477, consumption 350, lung diseases 282, diphtheria and croup 202, scarlet fever 65, typhoid fever 59, diarrhœal diseases 48, measles 35, malarial fevers 21, erysipelas 12, cerebro-spinal meningitis nine, small-pox eight, puerperal fever eight, whooping-cough seven, typhus fever three. From *diarrhœal diseases*, New Orleans 17, New York 13, Chicago five, Brooklyn and Boston four each, Baltimore two, St. Louis, Charleston, and Holyoke one each. From *measles*, Baltimore 14, New York 13, Philadelphia, Brooklyn, and Pittsburg two each, Chicago and Providence one each. From *malarial fevers*, New Orleans nine, New York and St. Louis four each, Brooklyn three, Chicago one. From *erysipelas*, New York five, Chicago three, Philadelphia and Boston two each. From *cerebro-spinal meningitis*, New York three, Chicago two, Philadelphia, Baltimore, New Orleans, and Nashville one each. From *small-pox*, New Orleans five, Philadelphia three. From *puerperal fever*, Chicago and St. Louis two each, New York, Philadelphia, and Brooklyn one each. From *whooping-cough*, Boston and New Orleans two each, New York, Brooklyn, and St. Louis one each. From *typhus fever*, New York three.

Six cases of small-pox were reported in St. Louis; diphtheria 51, scarlet fever 33, and typhoid fever 15 in Boston; scarlet fever 20, and diphtheria 11 in Milwaukee.

In the 73 cities and towns of Massachusetts, with an estimated population of 1,094,567 (estimated population of the State 1,922,530), the total death-rate for the week was 21.60 against 19.52 and 16.65 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending December 8th, the death-rate was 21.6. Deaths reported 3568: acute diseases of the respiratory organs (London) 448, scarlet fever 131, measles 98, whooping-cough 73, fever 59, diarrhœa 39, diphtheria 35, small-pox (Sunderland five, Birmingham four, Liverpool three, London two) 14. The death-rates ranged from 14 in Oldham to 32.8 in Preston; Bradford 16.6; Bristol 19.6; Sheffield 19.8; Nottingham 20.2; Leicester 21.4; London 21.5; Birmingham 21.8; Liverpool 23.6; Leeds 24.5; Manchester 26.1. In Edinburgh 17.9; Glasgow 23.5; Dublin 33.3.

For the week ending December 1st, in 169 German cities and towns, with an estimated population of 8,695,846, the death-rate was 23.4. Deaths reported 3913; under five years of age, 1763; consumption 535, lung diseases 445, diphtheria and croup 286, diarrhœal diseases 132, scarlet fever 85, measles and rötheln 84, typhoid fever 64, whooping-cough 58, puerperal fever 20, typhus fever (Stettin one) one, small-pox (Coblenz one) one. The death-rates ranged from 7.3 in Mannheim to 32.5 in Königsberg; Breslau 26.9; Munich 30.1; Dresden 27.2; Berlin 25.7; Leipzig 28.2; Hamburg 26; Cologne 22.7; Frankfort a. M. 16; Metz 15.1.

For the week ending December 1st, in the Swiss towns, there were 30 deaths from consumption, lung diseases 17, diarrhœal diseases seven, diphtheria and croup six, scarlet fever three, measles two, typhoid fever one, puerperal fever one. The death-rates were, at Geneva 12.3; Zurich 6; Basle 19.1; Berne 30.5.

The meteorological record for the week ending December 22d, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING DECEMBER 29, 1883.

GIHON, A. L., medical director. To the Naval Hospital, Washington, D. C.

RUSH, CHARLES W., passed assistant surgeon, U. S. S. Colorado. Granted sick leave for three months.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The *Section for Clinical Medicine, Pathology, and Hygiene* will meet at 19 Boylston Place, on Wednesday, January 9th, at 7.45 o'clock. Drs. F. I. Knight, J. P. Oliver, and T. A. DeBlois will open the discussion upon Follicular Tonsillitis, postponed from the last meeting. Dr. G. Liebmann will present a paper upon Spinal Irritation and Neurasthenia. Drs. J. J. Putnam and S. G. Webber will open the discussion. Dr. A. N. Blodgett: The Voluntary Abandonment of the Morphia Habit. Exhibition of two cases.

ALBERT N. BLODGETT, *Secretary.*

ERRATUM. — A correspondent calls attention to the fact that we were in error in our editorial of December 20th last, p. 594, first column, in stating that Andrews was sentenced to the State Prison for life. The sentence was for twenty years.

APPOINTMENT. — Dr. W. L. Richardson has been appointed Visiting Physician at the Massachusetts General Hospital.

BOOKS AND PAMPHLETS RECEIVED. — A Treatise on Bright's Disease of the Kidneys. Its Pathology, Diagnosis, and Treatment, with chapters on the Anatomy of the Kidney, Albuminuria, and the Urinary Secretion. By Henry B. Millard, M. D., A. M. With numerous original illustrations. New York: Wm. Wood & Co. 1884.

A Treatise on Syphilis in New-Born Children and Infants at the Breast. By P. Diday, Ex-Surgeon to the Hospital de l'Antiquaillé. Lyons. Translated by G. Whitley, M. D., with notes and an appendix by F. R. Sturgis, M. D. New York: Wood's Library. October, 1883.

A Treatise on Pharmacy: Designed as a Text-Book for the Student and a Guide for the Physician and Pharmacist, containing the officinal and many unofficinal formulas, and numerous examples of extemporaneous prescriptions. By Edward Parrish. Fifth edition, enlarged and thoroughly revised by Thos. S. Wiegand, with 256 illustrations. Philadelphia: Henry C. Lea's Son & Co. 1884.

Étude sur la Pharmacopée des États Unis. Par C. Tanret, Pharmacien de première classe, lauréat de l'institut.

Des Fumigations de Parfums Trochiques Désinfectants. Par C. Tanret.

Étude sur les Extraits de Quinquina. Par C. Tanret.

Medico-Chirurgical Transactions. Published by the Royal Medical and Chirurgical Society of London. Volume 65. 1882.

Same. Volume 66.

Voice, Song, and Speech. A Practical Guide for Singers and Speakers, from the Combined View of Vocal Surgeon and Voice Trainer. By Lennox Browne, F. R. C. P. Ed., and Emil Behnke. With numerous illustrations by wood-engraving and photography. New York: G. P. Putnam's Sons. 1884.

Sixth Annual Report of the Trustees of the Danvers Lunatic Hospital. For the year ending September 30, 1883. Public Document No. 20.

Hints in Sickness: Where to go and What to do. By Henry C. Burdett, Founder of the Home Hospitals Association for Paying Patients. Author of Pay Hospitals of the World. London: Kegan Paul, Trench & Co. 1883.

The Operative Treatment of Intra-Thoracic Effusion. By Norman Porritt, L. R. C. P. Lond., etc., etc. Being the Essay to which the Fothergillian Gold Medal, 1883, was awarded. London: J. & A. Churchill.

Establishment of Tent Field Hospitals for the Treatment of the Wounded on the Field of Battle. By B. J. D. Irwin, Surgeon and Brevet-Colonel, U. S. A., Medical Director Department of Arizona. (Reprint.) 1883.

Ominous Symptoms in Typhoid Fever. By Charles R. Crandall, M. D., Portland, Maine. A paper read before the Portland Medical Club, October 18, 1883. Portland. 1883.

Observations on the Use of Bromide of Ethyl as an Anæsthetic for Short Operations, and as a Precurser to the Administration of Ether. By A. E. Prince, M. D., Jacksonville, Illinois. (Reprint.)

The Electro-Osteotome. A New Instrument for the Performance of the Operation of Osteotomy. By Dr. Milton Josiah Roberts. New York. (Reprint.)

New Operation for Rupture of the Perinæum Through the Sphincter. By J. Collins Warren, M. D., etc., etc. (Reprint.)

Transactions of the American Dermatological Association at the Seventh Annual Meeting, Held at Lake George, N. Y., August 29–31, 1883. Official Report by the Secretary, Dr. Arthur Van Harlingen. Baltimore. 1883.

Index to the Transactions of the American Medical Association. Vols. I.–XXXIII. Prepared by William B. Atkinson, M. D., Permanent Secretary. Philadelphia. 1883.

Relation of Eye and Spinal Diseases. By A. Friedenwald, M. D., Professor of Diseases of the Eye and Ear, College of Physicians and Surgeons. Baltimore. (Reprint.) 1883.

The Illustrated Christmas Number of the Publisher's Weekly, 1883. New York: F. Leypoldt.

Ophthalmia Neonatorum and its Prophylactic Treatment. By Walter P. Manton, M. D. Boston. (Reprint.) 1883.

Charlatanism in Colorado. By Jesse Hawes, M. D. Greeley, Colo. (Reprint.)

Annual Report of the Society for Instruction in First Aid of the Injured. October, 1883. Published by the Society.

Report of Cases treated in Ward XIX. of the Royal Infirmary, Edinburgh. Reported by Skene Keith, M. B., C. M. Edinburgh. 1883.

Elements of Surgical Pathology. By Augustus J. Pepper, M. S., M. B. Lond., F. R. C. S. Eng., etc. Illustrated with eighty-one engravings. Henry C. Lea's Son & Co.: Philadelphia.

Report of the Commissioner of Education for the year 1881. Washington: Government Printing Office. 1883.

Principles of Theoretical Chemistry, with Special Reference to the Constitution of Chemical Compounds. By Ira Remsen, Professor of Chemistry in the Johns Hopkins University. Second Edition. Revised and enlarged. Philadelphia: Henry C. Lea's Son & Co. 1883.

Lectures.

SYPHILIS OF THE BRAIN AND MEMBRANES.

LECTURE II.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL.

BY H. C. WOOD, M. D.,

One of the Physicians to the Hospital, and Professor of Nervous Diseases in the University of Pennsylvania.

Gentlemen, — You will remember that when I last had the honor of meeting you we considered the subject of cerebral syphilis, with special reference to the disease as it affects the brain membranes. There is another form of specific disease of the brain which is much more rare. Cases of this form of cerebral syphilis are not often seen in the wards of a general hospital, but find their way into the insane asylums. I am, therefore, unable to illustrate my remarks by the presentation of a case, unless a brain which is now being removed from a man who died in the ward yesterday should prove to be the seat of this lesion. This man came into the hospital in a condition of absolute dementia. He was also partially paralyzed on one side. In the absence of any history it was, of course, impossible to make a diagnosis. The case, however, presented some of the aspects of the disease known as dementia paralytica, but later in the course of the lecture I shall bring the brain before you.

As I have said, I cannot illustrate my remarks by the presentation of a case, but in order to make the subject more complete I shall ask your attention for a few minutes to a consideration of syphilitic insanity dependent on disease of the gray matter of the brain. Sclerosis and atrophy of the gray matter are frequently found associated with disease of the membranes, and the cerebral symptoms which are present in disease of the membranes are always due either to primary or secondary involvement of the brain cortex or to derangement of its circulation. It is possible, however, for syphilis to attack the brain cortex without attacking the membranes. Under such circumstances the symptoms are not to be distinguished from the symptoms present in general paralysis of the insane. There is progressive mental failure, with a condition of depression, melancholia, or hypochondriasis, or with exalted delusions or mania, in which the patient thinks that he is the emperor, the czar, or that he owns millions, has great power, or strength, or, in some way, manifests the features of the *delire des grandeurs*. Then there is failure of muscular power, and fibrillar tremblings manifest themselves. The symptoms are sometimes not distinguishable from those of general paralysis of the insane, and it is often impossible in these cases to make the diagnosis from the symptoms alone. There may, however, be the evidences of syphilis of the membranes of which I spoke at the last lecture. If you have these you can make the diagnosis. But where the cortex is alone involved, it is not possible to determine the true nature of the lesion without a knowledge of the history or the aid of the therapeutic test.

At the last lecture I spoke of the therapeutic test of the existence of syphilis. Most of you know that this test consists in the power of the patient to bear mercury or iodide of potassium. In private practice it is my invariable rule never to ask questions in these cases. Persons are often unaware that they are suffering from syphilis. They honestly believe that they never had primary or secondary symptoms; these symptoms may, however, have been present, but so slightly marked as not to attract attention. Again, this is one of the points about which human nature often fails. People, even when death is staring them in the face, and their lives hang upon the truth, will make false statements. As we have a touchstone by means of which we are able to decide whether or not a patient is suffering from cerebral syphilis, I ask no questions, but apply the test where I have reason to suspect any disorder. It is a serious matter to mercurialize a patient, but it does no harm to produce iodism, so that when making the test I always employ iodide of potassium. If I find that ten grains three times a day produces symptoms of iodism I am almost sure that the case is not one of specific disease. If, on the other hand, the patient takes from one half to one drachm of iodide of potassium and waxes fat thereon, I am almost sure that he is the subject of specific disease. There are some persons, not syphilitic, who will stand large doses of iodide of potassium, but such cases are rare, so that when a patient will take half a drachm of the remedy three or four times a day it may be concluded that he is syphilitic. I say this with one reservation. Persons who have gradually accustomed themselves to the use of iodide of potassium, as, for instance, those who are asthmatic, will stand large doses of this drug, even when not suffering from syphilis. In such a case there will be the history of the long-continued use of the remedy. You must remember, also, that there is a syphilitic asthma, so that the relations of iodide of potassium to asthma are in many cases easily explainable. I shall speak of the method of using iodide of potassium when I come to consider the treatment.

It is important when employing iodide of potassium as a therapeutic test that you should be familiar with the symptoms of iodism. The most frequent manifestation of its constitutional action is the development of coryza, which exactly simulates that produced by cold. There will be dull aching in the temples, dependent upon congestion of the frontal sinuses, followed by a discharge from the nose, which is sometimes thick, but more usually watery, and often very free. In other cases, instead of coryza mild salivation is produced. When the salivation is severe the probabilities are that the patient has been taking mercury, and that the condition of the mouth has been produced by the liberation of the mercury which has been concealed in the tissues, for, as you know, iodide of potassium has the power of causing mercury which has been stored up in the body to take a soluble form. Sometimes an acne eruption is produced. Sometimes the eruption is of an ecthymatous character, while in other cases it takes the form of an erythematous dermatitis resembling erysipelas.

Before discussing the treatment of syphilis of the nerve centres I wish to say a few words in regard to the prognosis. Formerly when I took charge of a case of specific disease of the brain I always gave a favorable prognosis, but experience has shown me that sometimes such prognoses are not realized. Syphilis of the brain is a serious disorder, and in a certain proportion of cases you will fail to obtain the result you desire. The first element in the prognosis is the fact that because the symptoms are due to syphilis they are more amenable to treatment than if produced by any

other cause. Thus the fact that in any case insanity, palsy, or headache have a syphilitic origin makes them more amenable to treatment than if they were due to other causes. The prognosis must be guided by the manifestations in individual cases, but it always must be guarded. If a patient has severe hemiplegia, if the headache is severe, if the epileptiform attacks are violent, and if the history is that of long continuance, the prognosis is far more grave than if the nature of the disease is discovered at an early period of the attack. Even, however, in the most desperate cases almost complete recovery may be brought about by proper treatment. I remember reading in a London journal a short time ago the report of a case in which a man, absolutely paralyzed and demented, incapable of lifting hand or foot, and hardly knowing enough to have knowledge of his own existence, who in the course of a year or eighteen months was so far recovered that he won a rowing match on the Thames. Having made up my mind that the disease is specific, I tell the patient, no matter how severe the symptoms may be, "You have a chance for recovery." And however slight the symptoms may be I never say, "You are sure to get well." The proportion of chances, of course, varies with the extent of the lesion and the severity of the symptoms. It is a good plan to endeavor to put the prognosis in numbers. You make up your mind as to what you think the chances in his favor are, and then you tell the man, for instance, that he has three chances out of six. This satisfies him, and if he does not recover you simply say that he took one of the other three chances. It is related of a celebrated New York merchant that when on what he thought was his death-bed he asked his physician if he had a chance of recovering. The doctor told him that he had one chance out of a hundred. The merchant said that that was all right; he never wanted more than that in his business. He recovered.

Here is a patient whom I want to show you as a case of recovery. This man came into the ward two years ago. He then had severe specific basal meningitis with apparent implication of the brain substance. He had very marked oculo-motor palsy with ptosis and dilated fixed pupil on the left side. He had severe headache, great general weakness, and very little mental power. He had no epileptiform attacks. He suffered from a form of delirium which is seen in many of these cases, and is somewhat characteristic. During the day he would seem rational, but at night he would be dazed, not knowing what he did, and had a great tendency to get out of bed and wander away. When away from his bed he was unable to recognize where he was. It frequently happens in nervous diseases that the patient loses control of the sphincters, and passes urine and fæces in bed. In these cases of syphilitic disease this is not seen except in the last stages of the disorder. What we did see in this case was that the patient would go to a corner of the ward, and, supposing that he was in the water-closet, would void his excrement there. You see that there is an important distinction between these two conditions. In the one case the patient loses control over the rectum and bladder; in the other the patient does not recognize the position in which he is. Where you have this latter form there is always a suspicion arising that the disease is of a syphilitic origin. It is sometimes seen in general paralysis of the insane.

For several months this patient did not improve under treatment, but he is now almost recovered. The recovery is not absolute, and this happens in most instances of severe cerebral syphilis.

Here is a second patient who came in about two months ago. The disease was not so severe as in the previous patient, and it is probable that he will make a complete recovery.

In treating cerebral syphilis it is sometimes necessary to treat the symptoms, but the basis of the treatment is the use of antispecific remedies. If a patient has a violent attack of acute meningitis from cerebral syphilis, this is to be treated by counter-irritation or by bleeding, as may be indicated. If there is chronic or sub-acute meningitis or violent headache it is to be in part treated by the application of counter-irritants to the back of the neck and such other measures as are indicated; but although you do this you know that this is the mere frill, the *entrée* to the real courses of the dinner, and that the *pièce de resistance* is antispecific medication. There is no use of employing small doses in these cases; in order to cure the patient it is necessary to give large doses. This is one of the rare cases in which it can be truly said that the doctor effects a cure.

The question at once comes up as to the choice between iodide of potassium and mercury, and you will frequently find it somewhat puzzling to decide this point. Mercury is certainly more rapid than iodide of potassium, and when it is of great importance that the symptoms should be relieved at once, mercury should be used in preference to the iodide.

Some years ago I saw in consultation a tavern keeper in whom epileptiform convulsions had developed after he was forty years old. I diagnosticated cerebral syphilis, and he was put on the use of large doses of iodide of potassium. The fits grew less violent and came at longer intervals, and he was in a fair way to recover, and he would have gotten well, but one day he had a fit which stopped respiration a little too long, and he died. That man ought to have recovered, and he would have done so if it had not been for the accident of his death. If instead of giving iodide of potassium and being satisfied with a gradual improvement that patient had been mercurialized at once, the probabilities are that the fits would have been immediately reduced in severity, and he would not have died. You therefore see that we are to be guided to some extent in our choice between these remedies by the symptoms of the disease itself, leaving out of sight the condition of the patient. If the only manifestations of the disease are a little squint and a dilated pupil, we know that these will not kill the patient, and the slow action of iodide of potassium is sufficient. But where there are violent epileptiform attacks, or such a condition of the meninges that we fear the development of an attack of acute meningitis, mercury should be employed. In the great majority of cases it is sufficient to use iodide of potassium, but where there is any doubt, the administration of the iodide should be preceded by the use of mercury. Many combine these two remedies, but my own experience has not led me to have much confidence in this method. When the drugs are combined too small doses are usually given. If only ten grains of iodide of potassium are ordered, mercury should of course be given, but if one hundred grains of the iodide are given, I do not think that it is necessary to add to it one twelfth of a grain of the bichloride of mercury. If both are given at the same

time they should not be combined in the same prescription, for it is often desirable to push the iodide without increasing the dose of mercury. In regard to the amount given, my rule is to begin with small doses. If I am making the therapeutic test I begin with fifteen grains of iodide of potassium three times a day for a week. If a patient will bear this, he will in ninety cases out of a hundred bear sixty grains three times a day. In three or four days I increase the dose to twenty grains, and a few days later to twenty-five grains. If this is well borne, I make a bold plunge and give sixty grains three times a day. If the patient bears this the amount may be increased to eighty or ninety grains three times a day. If you want to cure cerebral syphilis there is no use in giving less than sixty grains three times a day. One half an ounce is not an excessive daily dose. This may be kept up for weeks, months, or years. How or why these large doses act better than smaller ones I cannot say, but I believe that iodide of potassium is one of the remedies that escape from the kidneys as fast as they are taken into the mouth, and do not accumulate in the patient's system.

In reference to the use of mercury, I do not think that it makes much difference how it is employed. It may be rubbed into the skin in the form of an ointment, it may be administered hypodermically in the form of the albuminate of corrosive sublimate, or it may be given by the mouth. If the mercury finds entrance to the system, it makes little difference by what door it goes through. If you want to impress the patient and do something that no one else does, of course you will use hypodermic injections, but these are apt to produce severe local soreness, and I do not think the effect is any better than when the drug is administered by the mouth. An important practical fact in regard to the use of mercury is that a mercurial course should always be followed by iodide of potassium. It is absolutely proven, to my mind, that mercury given for a long time does not all escape from the body, but finds its habitat in the solid tissues. I have seen patients mecurialized and recover, and when iodide of potassium has been given have a second outbreak of the former condition. In many cases, if the urine is examined no mercury will be found, but if iodide of potassium is administered, chemical tests will show mercury to be present. It should be made an absolute rule in all cases of syphilis to follow a mercurial course by a prolonged course of iodide of potassium.

The question always comes up in the treatment of syphilis, "How long shall the antispecific treatment be employed?" If you are giving iodide of potassium you can not continue the antispecific remedy too long. I think myself that in a severe form of cerebral syphilis the treatment should be continued for one, two, three, or four years after the subsidence of all symptoms. It is not then necessary to give it in such large doses as before recommended. Fifteen grains once a day is sufficient.

There are some cases of cerebral syphilis which will not respond to mercury or iodide of potassium. Under these circumstances the old treatment with the woods should be tried. A good form is Zittman's decoction. The compound decoction of sarsaparilla is the modern representative of mediæval decoction of the woods. I used to believe that these remedies had no power, and that sarsaparilla was a useless remedy. Although I now think that it is of service, I do not think that it is necessary in most cases of cerebral syphilis. In one case in which I failed with iodide of potassium and mercury, complete success followed the administration of Zittman's decoction. This preparation contains a small amount of mercury. The patient to whom I refer was a sea captain. I gave him iodide of potassium and I gave him mercury. He improved to a certain point, and then I could get him no further. In a moment of inspiration, or of desperation, I ordered Zittman's decoction. In a week the symptoms began to improve, and in four weeks he was able to return to his duties. The compound syrup of sarsaparilla is one of the few vehicles which has the power of covering the taste of iodide of potassium. In employing the iodide I order a prescription in which two drachms of the watery solution represents one drachm of the drug. I order the patient to add so many drops to one or two teaspoonsful of the compound syrup of sarsaparilla, or I administer it in the compound decoction of sarsaparilla. As iodide of potassium is prone to irritate the stomach, it should be given after meals, well diluted.

In this second patient we at first used iodide of potassium, but about ten days ago he was put on inunctions of mercury. These have been thoroughly carried out, and have produced a mild constitutional effect. He seems to have improved less under the mercury than he did under the iodide of potassium. We shall then resume the latter drug.

I shall now ask attention to the specimen to which I referred at the beginning of the hour. This is the brain of a man who was brought to the hospital on a stretcher ten days ago. The symptoms were those of complete dementia, but we had no history whatsoever. Three days ago he became unconscious; the temperature began to rise, and yesterday he died in a condition of apoplectiform congestion.

There is one point which I wish to refer to: that is, the rise of temperature. When in apoplexy, or apoplectiform conditions, the temperture begins to rapidly rise, the case almost always ends fatally. There is no symptom which has so fatal a significance as a rise of temperature accompanied with unconsciousness. The rapid rise of temperature indicates the destruction of so large an amount of nervous tissue, or tissue so situated, that recovery is next to impossible.

Looking at the specimen we find adhesions of the pia mater and exudations of small amounts of lymph on the upper surface of the brain. The under surface is normal, except that there is marked atheroma of the arteries. The arteries are thick, opaque, white, and feel like little round cords. This may depend on syphilis, and if the condition occurs in early life usually is so dependent; but as this patient was old, it may be simply the result of senile changes. Again examining the upper surface of the brain, I find, in the posterior lobe on the right side, a soft, discolored spot. I am sure that if some of this tissue were placed under the microscope numerous small, round cells would be found. This apparently is a gliomatous tumor of the brain. This consists of a tissue like sarcoma, with small, round cells infiltrating the brain tissue. There is no distinct line of demarkation separating the growth from the normal tissue. To the naked eye it differs from the normal brain structure only in color and consistence. On opening the right lateral ventricle I find it filled with serum. The left ventricle is empty. As I have said, I believe this to be a case of gliomatous tumor associated with secondary serous apoplexy.

A CASE OF CEREBRO-SPINAL SYPHILIS.

BY ABNER POST, M. D.

THE following case is presented with the knowledge that it is imperfect, but with the hope that it may prove as interesting to the reader as to the observer: —

J. D., aged thirty-one, Irish-American, of healthy family, and in general well until present trouble. Previous to March 31, 1867, served three years in the regular army, the latter portion of the time as corporal, — important matters of his personal history, as they establish the fact of physical soundness and of ordinary mental capacity.

After leaving the army John led an irregular and useless life; drank very freely, and was in general very dissipated. Had several gonorrhœas, and at some time not easily fixed, probably in the latter part of 1869 or early in 1870, had a venereal sore, followed by a bubo which suppurated and remained open for a year.

This was followed after a time by lumps in the throat and a falling of the hair. He did not consult a physician at this time, but applied nitrate of silver to the primary sore, cut his hair short, and took iodide of potash at the advice of a friend. He says he never had any eruption save a few pimples on his arms. Something, however, sent him once to the dispensary, and he took the contents of a bottle given him there. If he is to be believed the manifestations were very slight, and the treatment was certainly very imperfect. He was now for three years a barkeeper at the North End, and drank more freely than ever, being drunk by his own statement about half the time.

In the spring of 1875, or about six years, as nearly as can be ascertained, after the primary sore, he began to have dull remitting pains in various parts of his body. During the summer he was attacked on five or six occasions with a sudden sharp pain in the small of the back, which seemed to be drawing him backwards and compelled him to lie down to keep from falling. Each attack was of short duration; there was no loss of consciousness nor headache. He noticed after the commencement of the pains that he was dragging his right foot in such a manner that he wore out the tip of the right shoe. He lived at home at this time and was probably temperate, but his walk was so irregular that the boys on the street would cry out that John was drunk again. During this time, and probably before the commencement of these latter symptoms, he had some difficulty of micturition.

In November of the same year, 1875, the following note of his case was made by a physician who saw him: "Intellect below par; eyes dull, expression sleepy; gait labored, shuffling, slightly irregular; inclined to drag right toes; with difficulty stands on one foot with closed eyes; can turn round fairly; sensation in foot normal; slight incongruity of speech. Pulse 75; temperature 99° F. Urine contains no abnormal constituents." The patient is reported as saying that he had noticed a change in his own voice; words were thick and cut short, and he talked "through his nose."

Soon after this record he visited a sister in the country. One morning, after talking with the family until after ten o'clock the preceding night, he was unable to rise and his speech was unintelligible. In the afternoon he was encouraged to get out of bed, but was unable to stand and fell to the floor. In a day or two, however, he was able to return alone to the city. Nothing could be learned as to the extent of this attack or what members were involved.

He was treated for more than a year at various places, gaining slightly at times, but on the whole with no great benefit, and at last with marked failure. At one time his right arm became powerless, hanging helpless by his side; he regained partial control over it after a time, however.

Was first seen by the writer in the winter of 1876–1877. When first seen he was dressed and sitting in a chair, but was unable to hold himself upright in it; he could with difficulty stand erect for a moment without support; he could walk across the room when supported, dragging both feet, noticeably the right; tottered, and was easily upset. His grasp was very feeble, weaker on the left side than on the right. His mother dressed and undressed him, put him to bed, and fed him. On the preceding night he had fallen out of bed and was unable to return to it till assisted. He had entirely lost control over his sphincters. His countenance wore a vacant expression or a meaningless smile. His speech was thick, not easily understood. All answers to questions were followed by an idiotic laugh. There was a constant flow of saliva. His memory for the principal events of his life was good, and he could generally answer any question requiring a simple yes or no, but he was incapable of any mental effort. He could not give his age, but was very bright in his answers to questions for specific history.

Much of his time was spent in reading newspapers, which he comprehended, at least partially; but he could not repeat sensibly a single item. There was no delirium nor hallucination.

His tongue was protruded in a straight line, and no paralysis of facial muscles existed. There was no loss of sensation noticeable by ordinary methods of investigation. There was no wasting of separate muscles, and no tremor. A very slight cicatrix could be made out at the seat of primary sore; an irregular puckered cicatrix in right groin; aside from these no cicatrices; no enlarged glands; no nodes.

The irregular and progressive character of the paralysis, its union with dementia, in a patient of thirty-one, of probable syphilitic antecedents, made the diagnosis of cerebro-spinal syphilis nearly if not quite positive, and treatment was instituted in accordance with that view.

His improvement was almost immediate, and to a certain point rapid. In a few days he regained control of his sphincters and was able to dress and feed himself; his powers of locomotion returned more slowly, and he continued very silly. He became exceedingly restless, and as soon as he was able to go out of doors would spend the whole day from home, wandering as far as his strength would allow, returning always punctually at meal time.

Soon after he began to walk about the pain in the lumbar spine returned with great violence, and for a few days he walked with his back deeply curved — an opisthotonos — using his cane apparently to prevent falling backwards. His iodide was increased, and this symptom lasted but a few days, when he resumed his former position, still dragging his foot, his mental state improving little if any. What symptoms accompanied this condition of the spine are unknown, as during this time he was never found at home but only seen accidentally as he was walking upon the street.

During the summer he was seldom seen; he continued to take iodide, but irregularly, at times ceasing for a few days altogether. In the autumn he returned to treatment in about the same state as when last seen. He had had no further attack, but had made little if any improvement. He was put upon iodide again, beginning with fifteen grains three times a day, running up rapidly to half a drachm, and more slowly to one drachm.

On the 1st of January, 1878, he dragged his right foot for a few steps, and then raised it for a step. His intellect was somewhat clearer, he answered sometimes with the usual idiotic laugh, and sometimes in a more natural manner.

In the middle of January his laugh was still less marked. An acneform eruption existed on the face.

Dr. Wadsworth was kind enough to make an ophthalmoscopic examination of the patient for me, which was negative so far as symptoms of intra-cranial disease were concerned; he however found evidence of an old iritis in right eye of probable syphilitic origin. The following is his account: —

January 17, 1878.

Dear Doctor, — I examined the man you sent me yesterday. I found in the right eye evidence of former iritis and appearances about the optic nerve which may have been the result of an old optic neuritis or may have been congenital. The left eye was hypermetropic to a considerable degree, and, as he says it has always been, amblyopic. There were no evidences of disease to be seen in it.

The imperfect sight in the left eye I am disposed to believe connected with the hypermetropia, and both congenital.

If the appearances seen about the right optic disk are the result of former inflammation, I should rather regard that inflammation, here, as connected with the iritis which he certainly has had, than as a symptom of organic cerebral trouble. If neuritis were excited by the latter it would most probably affect both eyes. The iritis was probably specific.

I should call the result of my examination, so far as it bears on the existence of organic cerebral trouble, negative.

Very truly yours, O. F. Wadsworth.

Under date of , 1878, the following account appears: —

"At present he presents a most marked contrast to his former state. He drags his foot, but not so heavily as before, occasionally raises it for a few steps, especially if walking on a level floor. His eye is quite bright; he can talk for several minutes without the vacant laugh showing itself; he can write very intelligibly, probably as well as he ever did. He announces that "he feels better; that his mind is not troubled any longer," and that he could do almost anything he ever did. He remembers perfectly events previous and subsequent to his sickest time, but cannot believe he was ever unable to feed himself. Has noticeably improved within the last fortnight."

In regard to diagnosis the points particularly noticeable are the youth of the patient, the disorderly grouping of the symptoms, and particularly the evanescent and imperfect character of the paralyses, and the necessity of supposing various lesions, widely separated, as points of origin for the various symptoms. Such a history is very unusual, save as a result of syphilis, and even if the history of early symptoms were more imperfect than in the present case or entirely wanting, no other diagnosis would be admissible; the rapid though partial improvement confirms it.

An interesting point in the history of this case is the entire absence of headache and sleeplessness. Pain in some portion of the head of a very severe character is supposed to be an almost invariable precursor of cerebral symptoms. It is usually continuous, seldom intermittent, and usually without nocturnal exacerbations. Neither the patient nor his friends have the slightest recollection of its ever occurring, though questioned repeatedly in regard to it.

The pain over the lumbar spine was, however, one of the earliest symptoms; its severe character was the same as that usually ascribed to the cephalalgia, and may well supplant it as an early symptom.

The case unites three of the causes usually considered influential in determining cerebral symptoms in syphilitics: —

Poorly marked secondaries.

Irregularly followed treatment.

Irregular, dissipated life.

The first two antecedents may to a certain extent be considered identical. The slight severity of the symptoms being the reason why patients are unwilling to carry out the details of a specific course. That debauchery, and particularly the free use of alcohol, should tend to the location of syphilis in the nervous system seems but a natural result. It is the cause oftentimes of various nervous manifestations in other diseases, it renders the nervous system sensitive to outside influence, and exactly as syphilis often manifests itself at the seat of an old injury in the skin and bones, so it may tend to locate itself in a brain injured by the repeated hyperæmias of free alcoholic stimulation.

Hereditary predisposition to nervous diseases is also one of the determining causes, and it may be interesting to note that the patient's father, during the latter years of his life, was "nervous," according to his wife's story, that is, restless and irritable, less able to apply himself to his ordinary occupation than previously. These symptoms came on after, and were referred to, a blow on the head.

The dose of the iodide under which the first striking improvement was made is quite uncertain; a misunderstanding took place in regard to its administration; it fell far short of the enormous doses often necessary in cases of this character; it probably never exceeded fifteen or twenty grains three times a day. To it was added for a time a small dose of mercury; it was soon suspended, however. When the patient returned to treatment in the winter the dose was run up slowly from fifteen grains to one drachm three times a day, which he is now taking. There is little doubt in my own mind that had he taken at first the amount he was supposed to be taking the improvement would have been far greater.

His appetite was good throughout. No symptom of iodism appeared, save a few acne pustules on the face. The continuance of the very noticeable flow of saliva was suspected to be due to the iodide, but it markedly decreased during treatment.

The actual improvement made in the patient's condition almost surpasses belief. The long time that elapsed before he received continued specific treatment, and its insufficient character for some time after it was entered upon, certainly allowed sufficient time for permanent injury.

Of the later history of this patient I am able to give but little account. He remained in about the same general condition, never recovering sufficiently to assume again his position behind the bar, and finally died, probably some time in 1880. Of the particulars of his death I have no knowledge.

AN UNUSUAL OBSTETRICAL CASE.[1]

BY CHARLES P. STRONG, M. D.

THE case I bring to your notice to-night has its interesting features in the complications attending the confinement of a healthy primipara of thirty; these were: prolongation of the pregnancy and large child, entire absence of liquor amnii, interstitial and subserous fibroids, contracted pelvis combined with posterior position of the occiput, and non-rotation of the head; a list as formidable as it, fortunately, is rare.

Prolongation of pregnancy. Fortunately there is no possible cause for doubting the honesty of the patient's statement that menstruation was last observed September 17, 1882, and that impregnation must have taken place within the five days subsequent. Allowing the usual time of 278 days from the last appearance of the menstrual flow to indicate the time of delivery, June 22, 1883, was considered the probable date. There were, however, no signs of uterine action until July 10th, 296 days after the cessation of menstruation, and these were but false pains, and it was not until July 18th, 304 days from the end of the last period, and 299 days from the last opportunity for fertile coitus, that labor began. The influence of this prolonged period of gestation was undoubtedly manifest in the large size of the fœtus, eleven and one quarter pounds; but whether the absence of liquor amnii was cause or effect of the prolongation, or whether there was no relation between the phenomena except that of coincidence, I am unable to determine.

To abbreviate the account of the labor, let me state that the first thirty hours were occupied by irregular and infrequent, short, nagging pains, ineffectual in dilating the os much or rapidly, nor did they exhaust the patient, as she enjoyed the rest which chloral gave. The results of my first examination as noted were: First, the peculiar shape of the abdominal swelling. It was not a moderate curve from pulse to sternum, but hung pendulous, the umbilicus crowning the summit, like the tumor found in multiparæ with lax and ruptured abdominal walls. Though a tense, hard uterus, the position of the fœtus was made out with more uncertainty and difficulty than I ever before experienced, but I was sure the head was against the pubes, and the occiput in the right posterior position. The body it was impossible to locate, and, complicating still more, a hard mass the size and shape of a fœtal head could be felt in the median line just posterior to the uterine fundus, evidently imbedded in the walls of the uterus or else in its cavity. The question that these abnormal results of palpation offered was: were there twins, a monstrosity, or uterine fibroids to complicate delivery? With most careful auscultation I could find but one fœtal heart, beating most loudly on a level with, and just to the right of, the umbilicus, which made the existence of twins more problematical. By the vagina the head was felt presenting high up, the os just admitting the tip of the finger. As I stated before, there was no material change in this condition of affairs for some thirty hours; then the pains assumed a better character, and, the os slowly dilating, the head descended, pushing in front of it the anterior lip, which no efforts could keep replaced above the smooth brow, but which, happily, was not made at all œdematous by the pressure. When the os was dilated the head, although extended, firmly engaged, but in a curious manner, the brow jamming hard against the pubes, while the occiput was so far from the sacrum that the finger could easily be passed between them. So long as the pains continued to be effectual, although the progress of the head was very slow, I refrained from any interference to aid the occiput in rotating forwards, but when, with strong pains, there had been no advance for some time, I employed all manual means, pressures upon the forehead, attempts to bring down the occiput and the like, endeavoring thus to obtain better flexion to accomplish this end. No efforts on my part, nor the vigorous pains of the patient, could stir the head from the position it had then occupied for nearly an hour, and, realizing that a bladder slough must ensue unless a speedy termination was made to this localized pressure, I decided to etherize and deliver; but wishing first the advantage of a consultation, I summoned Dr. J. B. Swift, whose advice and manual assistance contributed largely to the happy termination of the case. Palpation under ether revealed the existence of but one fœtus, and the presence of large inter-uterine and subserous fibroids. The head was undoubtedly in the right posterior position, but the fœtal body was still obscured by the tense uterine walls. There seemed no reason for the non-advance of the head, except absence of rotation, and I hopefully applied the forceps with the idea of flexing the head and turning the occiput forwards, but in several trials failed to lock the blades, and, introducing my hand to ascertain the cause, came upon the too projecting promontory of the sacrum, between which and the pubes the head was caught, lying with its bi-parietal diameter in the narrowed antero-posterior diameter of the pelvis. As the forceps would not lock, version was attempted, and our united efforts succeeded in dislodging the head back into the uterus, turning and extracting, the most difficult part of the operation being to draw the body through after the feet were down, and the continued pressure upon the cord at this time is probably responsible for the birth of a fœtus whose heart was but feebly fluttering, and who, despite immediate attention, never breathed. The entire absence of liquor amnii permitted the uterine walls to mould themselves closely to the fœtal limbs, thus vastly increasing the tediousness and danger of version. The perinæum required no stitch.

Following down the uterus as the head was extracted I could force the fundus no lower than two inches above the umbilicus, and I introduced my hand, removing the placenta, completely into the uterine cavity before I could convince myself it did not contain another occupant, and that its size depended only upon the fibrous growths which extended throughout the posterior wall from the cervix to the fundus. The uterus was bulky as normally at the seventh month of pregnancy, and the mass that I had thought might be a fœtal head projected boldly from the fundus as a subperitoneal fibroid. Hæmorrhage, which I anticipated, fortunately did not occur. I administered a full dose of opium, and ordered the patient to be kept under its influence thoroughly.

The following day the patient had but slight tenderness over the abdomen, but the vulva was so swollen the legs were kept widely apart. Vaginal douches of carbolic were given for the lochia were already offensive, and ergot and quinine prescribed. Opium was continued to just short of narcotism. On the second day the uterus was still far above the umbilicus, the

[1] Read before the Section for Obstetrics and Gynæcology of the Suffolk District Medical Society, October 17, 1883.

lochia very copious and offensive, and about the perinæum and vagina sloughs appeared, especially deep on the perineal body. Abundant nourishment was taken. There was no material change until the fourth day, when the breasts, filling, were strapped. While the evening douche of carbolic, one to forty, was being given the patient suddenly collapsed profoundly, necessitating stimulants subcutaneously; immediately following was a prolonged chill, the temperature rose to 105.6° F., the lochia became very offensive, and a case of septicæmia seemed well started, but during the night all these bad symptoms disappeared, and the patient expressed herself as feeling better than at any time since delivery. The lochia, although profuse, were not offensive; the right labium was rapidly returning to its normal size; the sloughs had cleaned away and left granulating surfaces on perinæum and vagina. The left labium contained a hæmatoma the size of an orange, but day by day this diminished, and in six weeks entirely disappeared. On this day I substituted chlorinated soda for carbolic in the douche, and commenced to wash out the bladder for cystitis, a cystitis undoubtedly of traumatic origin. Three times during convalescence the copious lochia were stained with blood, and once the urine for five days was very scanty and dark, but contained no evidence of renal disease. Apparently this was an idiosyncrasy of the patient, for the same phenomenon was twice noticed two years ago when she was ill with acute rheumatism, and her urine then submitted to experts failed to show the cause. With these exceptions convalescence was uninterrupted. The uterus slowly involuted, and at the end of two months was but little above the pubes. Opium was omitted at the end of ten days, but ergot was retained, and materially aided in reducing the bulk of the fibroids.

The hæmatoma of the left labium, a lesion fortunately rare, and, unfortunately, not always as happy in its termination, was undoubtedly due to the sudden over-distention of the vulva by the passage of the large fœtus, and to the same cause I attribute the sloughs which appeared on the perinæum and vagina. The method of checking the milk by strapping the breasts firmly as soon as they began to fill, padding freely with cotton to secure uniform and elastic pressure, I regard as much more effectual and speedy than rubbing.

In conducting the convalescence no consideration perplexed me more during the first few days than that of the necessity for an intra-uterine douche which the very offensive lochia indicated. I determined against it for these reasons: Nothing in the general condition of the patient imperatively demanded it. The uterus was free from tenderness and the lochia so profuse I felt sure none were locked up in the uterine cavity, especially as I knew the placenta and membranes were thoroughly removed. The danger to my patient lay not so much in septicæmia as in peritonitis, and it seemed to me that the trying operation of washing out through the swollen and sensitive vulva, requiring, too, as it does, so much manipulation of the patient, would be provocative of far more serious trouble than it would ward off. The chill and high temperature on the fourth day might possibly have been due to the coming of the milk, and the antecedent collapse but a coincidence, but I am more and more inclined to attribute the entire disturbance to the entrance of some of the carbolic solution into the uterus. Since the intra-uterine douche and carbolic acid have grown into such general favor, every year shows an increasing record of cases of collapse, sometimes fatal, during its employment, this, too, notwithstanding the varied and complete armamentaria that abound in our surgical stores. With other disinfectants thus employed I never personally saw these unpleasant results, nor am I familiar with recorded cases. During my service as house officer at the Lying-in Hospital when intra-uterine douches were there first introduced, a solution of permanganate of potash was always employed, and in two severe epidemics of septicæmia where ten and more douches were daily given with no other instruments than a block-tin tube passed to the fundus and a Davidson syringe, there was never a bad symptom produced. I believe permanganate of potash is, above all others, the proper disinfectant for intra-uterine medication; the color of the returning fluid shows when the cleansing is complete, a very important consideration, because if done at all disinfecting needs to be thoroughly done; it does not produce colic, cramp, or systemic poisoning; the ensuing fall in temperature is more decided and protracted. I should always use it in vaginal douches, too, were it not that it stains the linen; for this class of cases a solution of chlorinated soda is most efficient, but the tendency of the latter disinfectant to form with pus a tenacious, semi-solid mass prohibits its intra-uterine use in sufficiently strong solution to be reliable.

The subinvolution of the uterus that persisted so many weeks is certainly explained by the presence of the fibroids, which acted not only passively by increasing the mass to be disintegrated, but even more potently retarded the retrograde changes by the reflex action of a foreign body in the uterine walls.

With the success of the early establishment of opium narcotism I am perfectly satisfied. The danger where so much manipulation is employed is not of septicæmia, especially if hands and instruments have been rendered aseptic, but of peritonitis. We have no other remedy to combat the inflammation when once established, and if checking peristalsis offers the one means of cure, checking it earlier rationally appears the one means of prevention.

The exhibition of ergot was continued two months, yet when I last examined the patient, eleven weeks after delivery, the cavity of the uterus measured two and three fourths inches, and the posterior wall and fundus were still thickened and irregular, although the projecting knobs that were so apparent immediately after labor had melted away.

To allot to each abnormal element its proper share in producing the complications of this case is impossible. Had any one of them existed alone a tedious labor would probably have been the worst result, but here it was demanded of a weakened uterus to force an excessively large fœtus, lying in an unfavorable position, through a contracted pelvis. Fibroids, wherever situated, tend always to produce trouble, the submucous ones especially predisposing to hæmorrhage. They impede the uterine contractions, frequently cause abnormal presentations, and during convalescence may threaten life by sloughing *en masse*, or, disintegrating more slowly, be absorbed and produce ichorrhæmia, a condition the prolonged elevation of the temperature shows was present in this case. In two previous cases where I observed this complication, the fibroids being of the subserous class, irregular and weakened uterine

action was the result; in one case forceps were required.

Reviewing my patient's symptoms I see that I might sooner have suspected pelvic deformity had there not, unfortunately, been so many other visible explanations of all irregularities. The pendulous abdomen, the malposition of the head, high up, and extended, with the brow pressed hard against the pubes, are all characteristic of this class of pelves, which Schroeder calls flattened pelves. They are produced by the sacrum being thrust forwards and downwards in youth, thus confining the narrowing to the antero-posterior diameter. The deformity is rarely marked enough to produce much trouble except in cases similar to the one under consideration, where there is relative disproportion between the diameters of the pelvis and a large fœtal head. It is in this class of cases that forceps often fail in consequence of the firm wedging of the head, in its wide bi-parietal diameter, between the pubes and the projecting promontory. Version offers far better prospects for speedy and safe delivery.

The temperature chart is instructive. The first days witnessed a steady rise in the temperature culminating on the evening of the fourth day at 102.5° F. It was on this evening also the patient had the chill and an accompanying temperature of 105.6° F. The next day there was a fall to 101° F., and during just two weeks there was a constant morning temperature of 100° F., and evening one of 101° F. For the ensuing two weeks there was a daily fluctuation from 99° F. to 100° F., then the temperature dropped to normal, and remained stationary. The constant elevation of temperature I attribute entirely to the great disintegrating mass of the fibroids.

NITRO-GLYCERINE AND THE CHLORIDE OF GOLD AND SODIUM IN THE TREATMENT OF ALBUMINURIA.[1]

BY ROBERTS BARTHOLOW, M. D., LL. D.

HITHERTO the therapeutics of renal diseases have not advanced in the same ratio as our knowledge of their pathology. It cannot be said now that a cure has been found, but that two remedies of real value are available. My contribution to this symposium, on albuminuria, consists in an attempt to define the place which these remedies should occupy in a curative scheme. To do this, in even the briefest way, I must clear the ground with a preliminary statement.

I start with the proposition that those renal lesions united by the common symptom — albuminuria — are of neural origin. There is a kinship between diabetes and Bright's disease. One of these is sometimes substituted for the other; and during the course of some rare cases of exophthalmic goitre this substitution occurs. Irritation of a certain part of the floor of the fourth ventricle is followed by glycosuria; of another part by albuminuria. The recent observations of Da Costa and Longstreth prove that a relation exists, whether casual or sequential, between certain renal lesions and degenerative changes in some ganglia of the abdominal sympathetic. The hypertrophy of the muscular coat of the arterioles, discovered by Dr. George Johnson, and the increased tension of the vascular system due to an irritation of the vaso-motor centre in the medulla, both present in the chronic forms of albuminuria, are further evidences of the agency of the nervous system. It was, more especially, the condition of elevated tension of the vessels which led to the use of nitro-glycerine. This remedy before all else reduces the vascular tension. It also lessens the work of the heart by removing the inhibition exercised by the pneumogastric nerve.

This remedy appears to have been first used by Mr. Robson, an English surgeon, in cases of albuminuria, and by him employed, because the high tension of the vascular system has proved to be so pronounced an element in the more chronic cases. I have, myself, seen some remarkable instances of relief — indeed of cure — effected by it. If time were now available, I could give some striking examples. In cases of mitral disease accompanied by albuminuria it also renders the highest service — for the diminished peripheral tension lessens the work to be done by the heart, and assists in the more equal distribution of the blood. The effect of this in relieving the renal congestion is obvious.

Chloride of gold and sodium has quite another function. It has long been known that this remedy has a special direction to the genito-urinary apparatus. The ovarian and uterine organs in the female, the testes and vesiculæ seminales in the male, are stimulated by it, and the kidneys, by means of which it is eliminated, and in which it tends to accumulate, are decidedly affected by it in function and structure. In common with some other agents of the class to which gold belongs — for example, corrosive sublimate — the chloride acts on connective tissue and checks its overproduction, or its hyperplasia. It would be quite impossible in this note to go over the evidence on these points, and hence I must ask your assent to these statements. They have been accepted as true of gold, from the days of the alchemists and iatro-chemists, as any one may ascertain from that curious collection of mediæval medical learning — the Anatomy of Melancholy. It has happened, strangely enough, that Hahnemann and his followers have profited by this knowledge, and have used gold preparations — especially *aurum potabile* — in the treatment of renal diseases with success.

How and when are these remedies to be used?

Nitro-glycerine is now administered, as all present know, in the form of the centesimal solution — one minim of the pure drug to 100 minims of alcohol. The initial dose of this one per cent. solution is one minim, which should be increased until the very characteristic physiological effects are produced. The susceptibility to the action of nitro-glycerine varies greatly, and hence the dose cannot be stated in advance. It is necessary to produce some obvious effect. To maintain the same level of action, a slight increase in the dose may be required from time to time. As the effect is not lasting, the interval between the doses should not exceed three or four hours.

The administration of nitro-glycerine should begin in acute cases immediately after the subsidence of the acute symptoms. It is indicated in chronic cases at all periods, but is more especially useful, if given before hypertrophy of the muscular layer of the arterioles has taken place. When it acts favorably, the amount of albumen in the urine steadily diminishes. The mechanism of its action consists in the lowering of the pressure in the renal vessels. How far any curative effect proceeds from action of this remedy on the sympathetic system remains to be determined.

[1] Read before the Philadelphia County Medical Society, December 19, 1883.

Chloride of gold and sodium is indicated in the subacute and chronic cases, especially the latter. The earlier it is given the better, if structural changes are to be prevented or arrested. The good effects to be expected from it will depend necessarily on the extent of the damage already inflicted on the kidneys.

The usual dose is one twentieth grain, twice a day, but this may be much increased, if necessary. At the outset, one tenth grain may be given; in a week the dose should be lowered to one fifteenth grain, and after a month the regular dose of one twentieth grain should be steadily pursued, with occasional intermissions. Indigestion, gastralgia, and colic pains, nausea or diarrhœa, are occasionally caused by it; and if so, the quantity administered must be reduced. It is usually borne without any discomfort, but after prolonged administration, salivation, weakness, emaciation, trembling and other nervous phenomena may occur possibly. Such effects, however, are wanting in my experience.

The treatment of albuminuria by nitro-glycerine and the chloride of gold and sodium does not necessitate the exclusion of other means — hygienic, climatic, or dietetic. These remedies should, however, be given uncombined at different hours, and their actions should not be hindered or obscured by the effects of other agents given with like purpose. To this general statement there may be two exceptions: with nitro-glycerine, amyl nitrite or sodium nitrite may be given; with the gold and sodium chloride, corrosive sublimate may be combined. If doubts may be felt in regard to the propriety of depending on the utility of these remedies, they need not be long experienced, for if no good effects are observed in two weeks they may then be discontinued.

REPORT ON OBSTETRICS.

BY C. M. GREEN, M. D.

THE DIAPHORETIC TREATMENT OF PUERPERAL ECLAMPSIA WITH HOT BATHS.

IN the last report on Obstetrics[1] was an account of six cases of puerperal eclampsia treated by Dr. Carl Breus with hot baths. To avoid repetition reference is made to that report for a description of the method adopted by Dr. Breus, together with his results. In a second paper[2] Dr. Breus has reported eleven more cases similarly treated with even better results than in the first series. Of these cases, the first eclamptic attack occurred in four, early in the first stage of labor; in two, after a long first stage; in one, during the second stage; and in four, in the first day post partum. The majority of the cases were severe: in only three instances, in which convulsions first occurred post partum, was a favorable prognosis warranted; yet of the eleven cases one only had a fatal issue. This patient, a primipara, aged nineteen, with albuminuria and œdema, was brought to the clinic insensible, having had her first attack two hours previously. Within two hours of her admission to hospital, during which time she suffered four attacks, she was delivered with forceps of a living child: the hot bath and subsequent wrapping up were then employed, and diaphoresis established: convulsions recurred but once thereafter. On the following day the urine was free from albumen, and the facial œdema had disappeared; but that evening the temperature rose to 104° F., and peritonitis developed which resulted fatally in three days: so that death was attributable only indirectly at most to the eclamptic condition. The other ten cases all recovered. Of the eleven children only two were lost, namely, by craniotomy.

Dr. Breus further testifies to the great value of this treatment as a prophylactic measure during pregnancy; not only in cases where the urine gives evidence of nephritis, but also in cases of albuminuria and œdema due to hydræmia, in which one apprehends cerebral effusion with consequent pressure and acute anæmia resulting in the eclamptic seizure. He has never known premature labor to have been induced by the baths, nor other unpleasant results to follow their use.

THE CERTAIN DIAGNOSIS OF PREGNANCY BEFORE THE APPEARANCE OF THE FŒTAL SIGNS.

Most authorities agree that the certain signs of pregnancy are all physical signs of fœtal origin; namely, the fœtal heart, the spontaneous movements of the fœtus perceptible to the physician, and abdomino-vaginal ballottement. Only exceptionally are any of these signs available before the sixteenth or eighteenth week; consequently the diagnosis of pregnancy before that time is only presumptive. Dr. F. Loviot believes, however, that "the existence of pregnancy can be surely recognized, at least ninety-five times in a hundred, before the appearance of the fœtal signs; at two months, two months and a half, *a fortiori* at three months and more;" and he writes[3] to maintain this thesis.

As the rational maternal signs afford only presumptive and confirmatory evidence, Dr. Loviot relies upon physical changes in the uterus which he appreciates by palpation, by the vaginal touch, and above all by conjoined manipulation. He agrees with Professor Pajot that the changes undergone by the cervix are not characteristic of pregnancy, but may be due to catamenial congestion, to metritis, and to various pathological conditions: he therefore directs his attention to the body of the uterus, which he believes is modified by pregnancy in a characteristic manner. By conjoined manipulation the superior segment of the pregnant uterine body is accessible above the symphysis pubis under the form of a rounded, depressible, elastic tumor: the inferior segment is depressed and enlarged, and broadened out of proportion to the cervix, so that it juts out, as it were, and forms around the base of the cervix a sort of cushion; a characteristic collar. As a whole the body of the gravid uterus is soft and elastic, and under the examining finger gives the sensation of pressure on a hollow rubber ball. This soft consistency exists at all accessible points; in front, behind, to the right and to the left. The examination necessary to appreciate these modifications ought not to cause pain. Neither uterine congestion nor chronic metritis, nor again fibroid tumors even when softened, impart identical sensations to the examining finger; although if pregnancy is complicated with uterine fibroma, the diagnosis will be more difficult.

CERVICO-VAGINAL LACERATION WITH RETROPERITONEAL HÆMATOMA AND EMPHYSEMA.

Dr. G. Bayer reports[4] two fatal cases of cervico-

[1] Vide vol. cix., No. 2, of this journal.
[2] Archiv für Gynækologie, Band xxi., Heft 1.
[3] Archives de Tocologie, Mai, 1883.
[4] Archiv für Gynæk., Band xxi., Heft 1.

vaginal laceration which possess very considerable scientific interest; not only on account of the rarity but also because of the similarity of the post-mortem appearances in cases differing widely in their ætiology and clinical course.

CASE I. An octavipara eight days before, and again on the day of, admission to hospital had uterine hæmorrhage: the os was about two inches in diameter, the placenta prævia, the fœtus in transverse position. A considerable hæmorrhage being excited by examination, and the pains being weak, a colpeurynter was introduced. One hour and a half later the colpeurynter was removed, and podalic version was performed through an os so small and undilatable as to require some force in introducing the hand: extraction was quickly performed without difficulty, and the placenta came spontaneously a moment later. The uterus contracted well; but very profuse hæmorrhage ensued from the posterior vaginal wall. An hour was spent in trying to check the hæmorrhage with sutures: the woman was restless and pale. Resort was now had to the tampon, and the hæmorrhage checked. Twelve hours later ensued dyspnœa, cyanosis, jactitation, and death from acute anæmia.

CASE II. A secundipara, aged twenty-four, hitherto in the best of health, was twenty-six hours in the first stage of labor at full term. While the head, after complete dilatation of the os, was passing normally and quickly through the pelvis, the woman suddenly grew pale and complained of ill-defined pain in the suprapubic region: the pulse was frequent. After the birth of the head there was felt above the symphysis pubis and to the right well marked crepitation. After the child was born, considerable blood mixed with air was expressed from the uterus, and the crepitation could no more be felt; but, although the uterus was well contracted, a profuse hæmorrhage continued, which however was checked with a tampon. Symptoms of septic poisoning soon appeared, accompanied by severe pain in the region of the right kidney: deep palpation from the right inguinal region upward gave a sense of soft resistance, and the uterus was pushed to the left. Death ensued two days after labor, from septicæmia.

Autopsy disclosed in both cases a right-lateral laceration of the cervix (in Case II. to the os internum, in Case I. to one centimetre below the os internum), and a tear of the vaginal vault without perforation of the peritoneal cavity. Through this tear blood and air bubbles had extravasated into the retro-peritoneal connective tissue and had extended upward along the psoas magnus to the region of the right kidney, pushing up the peritonæum. In Case II. the extravasation had degenerated into a dirty sanious pulp mingled with ill smelling gas.

These cases resemble others reported by McClintock, Hecker, Dohrn, and Löhlein in so far as lateral cervico-vaginal tears have given rise to the effusion of blood and air into the subperitoneal tissue; but in the hitherto reported cases, except one of Hecker's, the subperitoneal emphysema has been limited to the ante-uterine region. In Bayer's cases, on the contrary, and in one reported by Hecker,[1] air bubbles mingled with blood advanced along the psoas behind the peritonæum to the region of the kidney.

The treatment of such cases is well-nigh hopeless. The application of sutures to check the hæmorrhage is difficult; and if successfully performed, results in shutting up a quantity of blood and air to degenerate in a closed space: moreover, the opening of the vagina necessary to the insertion of sutures favors a further entrance of air: the antiseptic tampon therefore is to be preferred. A further difficulty lies in the fact that the air and blood are diffused in the connective tissue, and not confined in a sac which can be easily drained and irrigated: it is probable, however, that when death does not occur from hæmorrhage, the skillful introduction of a drainage tube and careful cleansing afford the best hope of success, as in complete ruptures of the uterus.

[1] Monatsschrift für Geburtshülfe, Band xxxi., S. 294.

THE ANATOMY AND ÆTIOLOGY OF RUPTURE OF THE PERITONEAL PORTION OF THE VAGINA DURING LABOR.

Of interest in connection with the last subject is a valuable paper by Dr. D. Berry Hart under the above title.[2] After pointing out the anatomical structure of the pelvic canal, Dr. Hart emphasizes the fact that whereas the anterior vaginal wall is strengthened by the bladder and urethra, and the inferior part of the posterior wall by the rectum and perineal body, the upper inch of the posterior wall is relatively weak. When, moreover, during labor the contracting longitudinal muscular fibres of the uterus exert upward tension on the cervix and vagina, the anterior vaginal wall suffers very little elongation, while the posterior wall is elongated to about five inches. If then the uterine tension is extreme, as in cases of fœtal mal-position, of faulty pelvis, or where the fœtal head is unusually large, the cervix or vagina, or both, will yield at the point that is structurally weakest; namely, as regards the vagina, at the upper part of the posterior wall.

Dr. Hart sums up the whole question as follows: —

"(1.) During labor the uterine muscle exercises an upward tension on the cervix and pelvic floor segments.

"(2.) The fœtal head exercises a dilating power on the cervix and pelvic floor segments, this dilating force acting at right angles to the long axis of the cervix and vagina.

"(3.) The vaginal walls are constructed so as to bear longitudinal tension and eccentric strain. This is provided for by the rugæ and the felted structure of the vagina.

"(4.) The anterior vaginal wall, from its close incorporation with the urethra and loose union with the bladder, is the strong wall.

"(5.) The posterior vaginal wall is structurally weak at its upper half inch, is more elongated during labor than the anterior one, and therefore —

"Rupture of the vagina is most common where the posterior wall is covered by peritonæum, and when it occurs is a tension tear like the cervical rupture."

THE PREVENTION OF OPHTHALMIA NEONATORUM.

Professor Credé, in a third paper[3] on this subject, has given the results of his further observation and experience. Concerning the ætiology of this affection he concludes: —

(1.) That the blennorrhœa of the newborn is caused by a specific virus identical with that of gonorrhœa.

(2.) That the virus, which is contained chiefly in the vaginal secretion of women suffering from vaginitis

[2] Edinburgh Medical Journal, July, 1883.
[3] Archiv für Gynæk., Band xxi., Heft 2.

granulosa, comes in contact with the conjunctivæ during the expulsive stage for the most part: consequently.

(3.) That a protracted expulsive stage (and Credé considers the period protracted if over one hour in duration) favors the inoculation: further,

(4.) That rupture of the membranes more than three hours before the birth of the child not only prolongs the labor and thereby increases the opportunity for infection, but also renders it possible for the examining finger to carry the virus to the eyes of the child: also, —

(5.) That as boys are in the average larger than girls and therefore, *cæteris paribus*, entail a longer expulsive stage, they are more liable to be infected than girls.

(6.) That the incubation stage of the virus is at most not longer than five days; and that consequently blennorrhœa appearing later than five days after labor must be attributed to post-partum infection by the unclean fingers of mother or nurse, or by contact with infected sponges or linen.

(7.) That the normal secretion of the vagina cannot cause a specific blennorrhœa, but may give rise to a simple catarrh.

After trial of various methods, Credé now employs the following treatment: After the cord is cut, the child is bathed and the eyes cleansed with a bit of cloth and pure water: the lids are then separated a little, and by means of a glass rod a single drop of a two per cent. solution of nitrate of silver is allowed to fall upon the cornea. With the great majority of children no reaction follows this application; but in some cases, especially in those of premature birth, there appears several hours after the application a slight hyperæmia of the conjunctivæ without swelling, and a somewhat increased secretion: these appearances vanish, however, on the third day at the latest without treatment. Credé still employs the vaginal douche for the sake of cleanliness; but he does not think it has any especial value in preventing fœtal inoculation. Before the introduction of this method into the Leipsic Lying-in Hospital, blennorrhœa was observed in about ten per cent. of all cases: since June, 1880, when the measure was systematically adopted, the proportion has fallen to about two tenths of one per cent. A more favorable result could scarcely be expected.

FORCEPS IN BREECH PRESENTATIONS.

Prof. W. T. Lusk has reported[1] to the Practitioners' Society of New York a case in which he applied forceps to the breech. A primipara, aged thirty-two, had had a long first stage, when the cessation of pains made operative interference necessary. The breech presented high up in the pelvic cavity with both thighs flexed. Unsuccessful effort was made to extract the breech by traction with the index fingers hooked into both groins: it was then decided to try forceps. One blade of the ordinary Simpson forceps was applied over the sacrum, the other over the posterior surface of the opposing thigh. The forceps did not slip: the breech was brought to the perinæum, and a living child weighing eight pounds was delivered in fifteen minutes from the beginning of the operation. The only injury occasioned by the forceps was a slight abrasion of the abdomen, which healed quickly.

Hospital Practice and Clinical Memoranda.

SALIVARY CALCULI OF THE RIGHT SUBMAXILLARY GLAND.

BY J. BRADFORD COX, M. D., SAN JOSE, CAL.

MR. J. D., aged fifty-two years, born in Prussia, single, a mechanic, in January, 1879, had an inflammation of the right submaxillary gland, which lasted two or three weeks. The abscess which resulted, instead of breaking externally, notwithstanding poultices to promote it, discharged very freely through Wharton's duct. There was a continuous discharge of pus through that duct until May 29, 1882, when he called at my office for treatment.

An examination showed the gland to be a very little larger than normal and indurated. Pressure on it caused pus to flow from the outlet of the duct near the frænum linguæ. An ordinary silver probe passed readily along the course of the duct to the gland. The touch revealed either necrosed bone or a calculus, the removal of which I assured him would be necessary before he could recover.

As he had consulted several other physicians, and used various remedies without benefit, he consented to an operation. This consisted in cutting into the gland from the inside of the mouth with an ordinary bistoury, wrapped with a roller bandage except at the point. The end of the probe, passed through Wharton's duct, served as a guide. When the opening was large enough I introduced a pair of bullet forceps and removed two calculi. The larger is irregular in shape, with a smooth surface on one end; the remainder of the surface is quite rough. It is thirteen millimetres long, eight broad, and seven thick. The smaller is flat shaped, smooth on one side, where it probably rested against the other. There is a similar smooth place on the end of the larger which corresponds in shape and surface with this. It is rough on the other side and edges. It is seven millimetres long, five broad, and two thick. They are dirty brown in color; the rough projections lighter than the dark background; very hard, having the appearance of brown quartz on the smooth surfaces. Internally the larger one is snowy white. It shows under the microscope an amorphous scaly detritus, many of the fragments having the shape of the epithelium from the mucous membrane of the mouth, but no definite forms of crystallization.

At the time of writing the patient is entirely well. The duct is larger in calibre than normal; and the gland secretes what appears to be healthy saliva, which can be pressed out through the duct.

— The statement of the *British Medical Journal* that its weekly issue amounts to eleven thousand six hundred and fifty copies — a "circulation about equal to the combined circulation of all the other weekly medical journals published in England" — seems a little startling until it is remembered that the British Medical Association numbers ten thousand and fifty, to each of whom a copy is furnished. It follows that its circulation among non-members, including the exchange list, amounts to about sixteen hundred.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

J. B. SWIFT, M. D., SECRETARY.

OCTOBER 17, 1883. DR. C. P. STRONG reported

AN UNUSUAL CASE OF OBSTETRICS.[1]

DR. SHERMAN asked if there was any hæmorrhage from the fibroids.

DR. STRONG said there was none. He feared there would be, and ergot was given immediately after delivery with the idea of preventing it.

DR. SHERMAN asked if any bad effects were seen from the continued use of ergot, and spoke of a case where the continued use affected the sight, the trouble stopping on discontinuing the drug, and being reproduced when the medicine was resumed.

DR. STRONG said he had never seen any trouble himself, but had seen cases of the kind reported. In one case he had given it continuously for seven months without any bad effect. At first it was given for two weeks, then stopped for a few days, and then resumed, but finally it was taken continuously.

DR. SHERMAN asked the strength of the solution of chlorinated soda.

DR. STRONG replied at first he used one to ten, but this being too strong it was reduced to one to twenty, which was very grateful to the patient. He used two quarts of the solution four times a day. In intra-uterine injections he would not use it because if there was any pus present it would make a coagulum which might obstruct the canal.

In regard to the collapse, he attributed it to shock caused by the carbolic acid solution entering the uterus.

DR. SHERMAN said that while he was at the Lying-In Hospital he had given a great many intra-uterine douches of carbolic solution. At first they were given very hot, temperature of 115° F. or 120° F., and with these he had seen cases of collapse. Afterwards the temperature was reduced to 105° F., and no cases of collapse were seen. He thought the symptoms were caused rather by the heat than the carbolic acid.

DR. COBB said he had frequently applied pure carbolic acid and a solution of equal parts of carbolic and glycerine to the interior of the uterus, and had never had any bad effects from it.

DR. STRONG replied that carbolic acid of full strength would have such an effect on the mucous membrane, smearing it over with a coagulum, that absorption would be prevented. In these cases the symptoms were not seen, but were produced when the carbolic was in a weaker solution.

DR. SHERMAN asked if there had been any symptoms of poisoning after the shock.

DR. STRONG answered there were none. Several days after there was a scanty flow of dark-colored urine, which at first he was inclined to attribute to the carbolic, but as the patient had the same thing when no carbolic had been used he did not think it could have been due to that.

DR. COBB said he used carbolized douches in all his cases, and had never seen any bad effects from them.

DR. STRONG said he never had before this case, but now he had concluded never to use carbolic acid for these douches. He thought there were other disinfectants which were just as effectual, and from the use of which such symptoms had never been reported.

DR. LIEBMANN asked if these symptoms might not be due to the fluid passing through the Fallopian tubes.

DR. STRONG replied that in the puerperal uterus where the os was so widely open, allowing a free exit, it must be extremely rare, but in the non-puerperal uterus it might happen.

DR. LIEBMANN spoke of an article which he had recently seen where the idea was advanced that the hot douches caused an acute inflammation in the mucous membrane, this causing œdema which prevented hæmorrhage by pressure on the vessels, and the shock which was sometimes seen was caused by this acute inflammation.

DR. SHERMAN asked if there was any post-partum hæmorrhage.

DR. STRONG said there was none. Fifteen minims of Wyeth's aqueous extract of ergot was given subcutaneously as soon as the placenta was removed.

DR. STRONG spoke of putting the patient under the influence of opium immediately as a preventive measure in cases where peritonitis is feared. In his case the patient was given opium enough to just affect her without narcotism, and this was kept up for ten days. She did not complain of a pain, nor was there any tenderness following the manipulation.

DR. E. O. OTIS asked what Dr. Strong would use as a vaginal injection.

DR. STRONG replied that in both his obstetric and gynæcological cases he used a solution of chlorinated soda. There was one objection to it, its odor, which resembled iodoform. He had never used boracic acid as a vaginal injection, but had used it in cystitis. He used a saturated solution with enough hot water added to raise it to the required temperature. He spoke of a case of paralysis of the bladder where this solution was used as a preventive. As long as the bladder was washed out with it there was no trouble, but on discontinuing the acid cystitis developed, which was stopped by renewing the acid washings. He did not think it was a sufficiently powerful antiseptic for vaginal douches.

DR. COBB asked if Dr. Strong used vaginal douches in all cases of labor.

DR. STRONG replied it depended on the attendants. If they were sufficiently intelligent and reliable he used the douches, but if they were not he merely had the genitals bathed with some antiseptic solution. He thought that among the better class of patients they would consider themselves neglected unless the douches were given. In cases where intra-uterine douches were needed he always gave them himself.

[1] See page 30 of this number of the JOURNAL

RHODE ISLAND MEDICAL SOCIETY.

THE usual quarterly meeting of the Rhode Island Medical Society was held in Providence, December 20th, the President, DR. JOB KENYON, in the chair.

The secretary being absent DR. F. B. FULLER, of Pawtucket, was appointed secretary *pro tem.*

As recommended by the Board of Censors, Drs. Clarence M. Godding, of Providence, and Philip K. Taylor, of Kingston, were admitted to fellowship.

THE MEDICAL EXAMINER QUESTION.

DR. LLOYD MORTON, of Pawtucket, read the report of the committee on the proposed law providing

for medical examiners and abolishing the office of coroner in this State. The report included the draft of a law modeled after the medical examiner system of Massachusetts, but adapted to the legislative and judicial systems of Rhode Island.

The proposed act was attentively considered by the Society, and will be submitted to the General Assembly in January.

A suggestion to expunge the name "medical examiner" and retain "the venerable title of coroner" was not favorably received. The committee who drafted the act, together with the President, were elected the committee to present the subject to the attention of the General Assembly.

Dr. D. H. Batchelder, of Cranston, read a paper on the Pathology and Treatment of Inflammation.

Dr. Herbert Terry, on behalf of Dr. A. D. Weeks, in whose practice the case occurred, reported

A CASE OF TUBAL PREGNANCY,

and exhibited the specimen. The patient was healthy, aged thirty-two, married two years, and eleven months before this illness had a normal confinement. The symptoms were sudden and severe. At four P. M. she felt a pain in the right ovarian region accompanied by faintness and vomiting. At seven P. M. there was a collapse, and she died four hours later.

At the post-mortem examination the abdominal cavity was found filled with blood. There was a rupture of the right Fallopian tube, within which was the fœtus. The fœtal head presented at the opening, which was about the size of a silver three-cent piece.

The following points were the most important[1]:—

(1.) The thinned edges at the point of rupture.

(2.) The decidua in the uterine cavity.

(3.) The partially developed placenta and the chorion villi in process of atrophy.

(4.) The corpus luteum in the ovary of the opposite side.

Dr. Anita E. Tyng, resident physician and superintendent of the Woman's Hospital in Philadelphia, reported three cases of ovariotomy.

ANEURISM OF THE THORACIC AORTA.

Dr. Charles O'Leary reported the following case:—

A man, thirty-four years of age, had suffered from continual pain in the back for four years. All through his illness there had been a pulsation in the lumbar region strong enough to visibly lift the fingers. There was no bruit. Aneurism was suggested, but its origin could not even be guessed. Several eminent physicians saw the case, and all agreed that, the possibility of aneurism excepted, it was a case of transmitted pulsation. The pain in the back was at times severe, extending into the left gluteal region and along the course of the sciatic nerve. It was worse if the patient moved about, and he was often compelled to stop and stand awhile when on the street. He used morphia hypodermically.

He was last seen by Dr. O'Leary five days before his death, and was then suffering intensely from pain in the back and left knee, for which two and a half grains of morphia were given before ease was obtained. A tumor could be felt through the abdominal walls, apparently connected with the left psoas muscle. The patient died in a convulsion.

At the autopsy an aneurismal sac was found extending from the eleventh dorsal to the fifth lumbar vertebra. The eleventh and twelfth dorsal and fourth and fifth lumbar vertebræ were eroded, and there were a few loose pieces of bone. The left psoas muscle was pushed outward and greatly thinned. The sac extended somewhat to the right of the spine in the dorsal region, and communicated with the lower part of the thoracic aorta just above the diaphragm on the left side. The sac had not ruptured.

The President appointed delegates to other State medical societies as follows:—

Maine, Drs. G. W. Porter, of Providence, and D. O. King, of Pontiac. New Hampshire, Drs. C. H. Fisher, of Providence, and Ariel Ballou, of Woonsocket. Vermont, Drs. E. M. Snow and C. H. Leonard, of Providence. Massachusetts, Drs. O. W. Brown and A. E. Ham, of Providence. Connecticut, Drs. G. T. Swarts, of Providence, and F. J, Smith, of Coventry. New York, Drs. G. P. Baker and E. T. Caswell, of Providence.

Following adjournment the Society was entertained by the President.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.[2]

C. B. NANCREDE, M. D., RECORDER.

Thursday evening, December 13, 1883. Dr. J. H. Musser in the chair.

CALCIFIED PERICARDIUM. DOUBLE MITRAL DISEASE.

Ella S., white, aged twenty-three, was admitted to the University Hospital in September, 1880, complaining of palpitation and dyspnœa, and suffering from an œdematous and eczematous condition of the lower extremities. She was a girl of regular habits, somewhat exposed to changes of weather and to wet, doing no very hard work. She had had the diseases peculiar to childhood, but never rheumatism nor chorea. Her father had had acute articular rheumatism, and died suddenly; beyond this there was nothing peculiar in the family history. Three years before admission she first noticed slight palpitation and dyspnœa on exertion. For some time before that she had been subject to frequent attacks of epistaxis. One year afterward dropsy appeared in the ankles, and spread upward. The palpitation and dyspnœa became more troublesome, her flesh and strength failed, and she was compelled to quit work and come into the hospital. When first seen she was pale, anæmic, weak, breathless on exertion. The heart's apex beat was in the seventh interspace, one inch outside of the nipple line; action strong and heaving. Best heard over the apex beat, but transmitted feebly up toward the base of the heart and well out into the axilla, was a loud, blowing systolic murmur. There was no pain in the heart nor tenderness on pressure over it, nor had there ever been. Over the lungs were scattered moist râles; the respiratory murmur was harsher on the left than on the right. Cough was slight with some mucous expectoration. The lower extremities were œdematous, and the abdominal cavity about half filled with fluid. The liver was slightly enlarged. The urine was normal in quantity, and contained neither albumen nor casts.

[1] Cases recently reported: D. D. Gilbert, M. D., Boston Medical and Surgical Journal, December 6, 1883. C. H. Briddon, M. D., New York Medical Journal, December 8, 1883.

[2] Continued from page 17.

Under treatment the urine became copious, the œdema gradually disappeared, and the heart action became stronger and more regular. In a few days friction sounds appeared at the base of the right lung. Any slight exposure would bring on an attack of intense congestion of the lungs with dyspnœa that often threatened life, and with these attacks there was often congestion of the kidneys with suppression of the urine. Between the attacks the heart retained its power well, though it slowly dilated. At intervals she complained of dull pain in the hepatic region. The rough respiration noted at first over the left lung became more and more marked till finally over a small area just below the spine of the scapula it had developed into bronchial breathing. Friction sounds came and went. There were always moist râles scattered through the lungs. The expectoration was mucous or rarely muco-purulent. Three months after she came under observation there was developed at the second right intercostal space, and carried out into the arteries of the neck, a systolic murmur differing in pitch and tone from the mitral systolic. About this time, too, she complained of pain in the heart whenever its action was excited. Soon afterward albumen was found in the urine, but no casts; this was the only time it was ever detected. Fourteen months after she was first seen there was noticed just inside the apex beat, and carried indistinctly toward the base, a harsh, short murmur, immediately preceding the systolic murmur, and separated from it by an exceedingly short but appreciable interval. This murmur was noted on several occasions afterward, but was much more frequently absent than present. Its appearance and disappearance seemed to be attendant on no definite conditions. Soon after it was first noticed she had several attacks of epistaxis, and afterward occasional slight hæmorrhages from the lungs. She was discharged in March, 1882, and was readmitted last September. She had been gradually losing ground. Seven months before she took cold; the dropsy returned and persisted. When seen the whole body was œdematous, and the abdomen enormously distended. The apex beat was in the fifth interspace in the mid-axillary line. The systolic murmurs were, perhaps, louder, but beyond this had not changed. Over an area between the left nipple and the sternum was heard a harsh, low-pitched, presystolic murmur. It was much more apparent than the former presystolic murmur, but had the same characters. Its point of maximum intensity was just to the left of the sternum. It was constant. The respiratory murmur over the left lung was very much harsher than over the right. Below the spine of the scapula the breathing was sometimes blowing with mucous râles, sometimes cavernous with gurgling râles. The expectoration was mainly frothy mucus. She died three weeks after admission in a fit of dyspnœa.

Autopsy seven hours after death. General dropsy, most marked in the lower extremities and genitals. On the lower part of the abdomen there is a marked varicose condition of the cutaneous lymphatics. Cavity of the pericardium is completely obliterated by adhesions. The two pericardial surfaces and the fibrous tissue connecting them had been changed into a calcareous plate, three inches broad, completely encircling about its middle the heart with the exception of a space one inch wide on the posterior surface of the left ventricle. This calcified condition extended for one inch on the anterior surface of the pulmonary artery. The heart, with the calcified pericardium, weighed twenty-eight ounces. The auricles were dilated, their walls thinned. The ventricles were dilated, their walls thickened and undergoing fatty degeneration. The leaflets of the mitral valve were thickened and rigid; the mitral orifice was very decidedly narrowed. In the inner surface of the left auricle were several calcareous patches. The aorta was very small, scarcely admitting the index finger, and showed patches of atheroma. The lungs were chronically congested and œdematous, the condition being most marked on the left; there was no breaking down of their substance. The abdomen contained five gallons of straw-colored serum. The peritonæum was thickened and roughened. The liver weighed three and one half pounds, and was cirrhotic. Its capsule was much thickened and adherent to surrounding structure. The mucous membrane of the stomach was mammillated and thickened. The kidneys showed cyanotic induration.

SECTION OF FIBROMA MAMMÆ.

Presented by DR. MACCONNELL for Professor Pancoast.

The patient was twenty-two years of age, and the growth was of seven months' duration. Fibromata of the breast are very frequently found, although some English authorities consider them to be of rare occurrence. They have been variously described under different names by writers. Birkett considers them a form of adenoma, Broca, adenoma with predominance of stroma, etc., etc. This tumor was of an ovoid shape, firm and elastic, and on section presented a maroon-colored tissue, which under the microscope is seen to be composed of dense bundles of mature fibrous tissue with but few nuclei. In some portions bands of wavy connective tissue are seen. The epithelial elements of the acini are hyperplastic.

SECTION OF LARGE SPINDLE-CELLED SARCOMA OF LOWER JAW.

Exhibited by DR. MACCONNELL for Professor Pancoast.

The patient was a man aged twenty-four years. The growth had existed for about three years. The egg-shell crackle was readily elicited, the growth being of central origin. On section it presented a whitish appearance, and was permeated by spiculæ of bone.

LIVER OF CHICKEN WITH TUBERCULAR GROWTHS.

Exhibited by DR. MACCONNELL.

The microscope clearly proved the nature of the growths.

DR. FORMAD had seen four or five similar cases in chickens, and two in turkeys, in all of which he had detected tubercle bacilli.

DR. BARTON was much interested in two of the specimens presented by Dr. MacConnell. He was much surprised as to the nature of the tumor of the jaw, in that it was a spindle-celled and not a giant-celled sarcoma. Its site and duration would clinically have clearly indicated one of the myeloid variety. The sections of the mammary growth differed from those examined by him in that in adeno-fibroma the glandular elements were more evenly distributed, whereas this section reminded him of his former studies of an elderly normal gland, such large tracts are found without any traces of gland tissue; whereas in

all adeno-fibromas examined by him the adenomatous and fibrous elements were relatively more evenly distributed, giving the idea of the neo-genesis of both, and not the atrophy of one, and the proliferation of the other.

Recent Literature.

Surgical Applied Anatomy. By FREDERICK TREVES, F. R. C. S., Assistant Surgeon and Senior Demonstrator of Anatomy at the London Hospital, etc., etc. Illustrated with sixty-one engravings. Philadelphia: Henry C. Lea's Son & Co. 1883.

This little volume pleases the eye by its neatness and compactness, and we are glad to find the pleasant impression much strengthened by a perusal of its contents. Many writers have of late attempted the difficult task of writing an Applied Anatomy, the need of which is felt more and more every day. There is an increasing and perfectly justified aversion to the insistence on dry and useless details which are frequently taught simply because they are in the books. *Facile princeps* among recent works on anatomy as applied to surgery stands Tillaux's Anatomie Topographique, but it is large and in a foreign language. Mr. Treves has given us an excellent addition to our library by writing a book that is not one on surgery, but one on anatomy, bringing out its surgical applications. We think it very much to be regretted that he has given but passing notice to its medical applications also. He might have done so without making the book unwieldy, and then it would have been invaluable as a text-book on topographical anatomy. As it is it goes a long way towards supplying a want. Mr. Treves is well read in the anatomical and surgical literature of other countries. His illustrations are for the most part taken from the works of Braune, Rüdinger, Tillaux, and Agatz. We notice a rather curious mistake about the *calcar femorale* of Merkel or the "true neck of the femur" of Bigelow. Mr. Treves ascribes its discovery to Merkel, and refers to the *American Journal of Medical Sciences* of 1874, which can have contained at most only an abstract of the paper which appeared in *Virchow's Archiv* of that year, not apparently being aware that the structure had been described by Bigelow in 1869. Probably it is through an oversight that he describes it as being on the anterior instead of the posterior part of the neck of the femur. It is a serious error to state that the pleura descends behind only to the spine of the eleventh dorsal vertebra, as it has been found as low as the transverse process of the first lumbar. We are inclined to question the statement that the quadratus lumborum is not usually cut in colotomy, and regret that the author does not point out the frequency of a mesentery to the descending colon. The surface anatomy of the different parts is generally duly discussed, but we should have liked a section on the back as a whole according to the plan pursued by Holden. We regret that the mediastina are barely noticed. It is incorrect to say that the trachea is immediately in front of the œsophagus in the neck. The section on the head is in many respects excellent. Taken as a whole the book is very satisfactory. To be sure there are mistakes and omissions, but it is a good and useful compilation that we believe will be very popular among students. We cannot close, however, without wondering what would have been the fate of an American at the hands of English critics, should he say that an organ "has been found herniated" (page 325). We trust this expression will be found "herniated" *out* of the future editions which we hope to see of Mr. Treves' book.[1] T. D.

— Professor Huxley, at a recent meeting called for the purpose of ameliorating the condition of the population of the East End of London, narrated experiences which could be duplicated by many who have been engaged in dispensary practice in the great cities of this country, but who may not know that they have so illustrious a *confrère*. Professor Huxley said: "Some forty years ago I was very familiar with certain portions of the East End, — one of those waterside portions where you find all the peculiar conditions of the East End in their typical state. I was at that time engaged in the business of my original profession of medicine, and it was my duty to attend the poor of the parish in that particular region. I therefore became familiar with their lives in a manner which is rarely possible to any but the clergyman and the doctor. I remember as if it were yesterday the condition in which a great proportion of those people lived, and it was such that I found in those recent statements which have been brought before you nothing specially novel and nothing unfamiliar. A great majority of the persons who used to come to me complaining of this and that were simply undergoing slow starvation, mitigated by bread and the stuff to which they gave the name of tea. I remember as if it were yesterday a poor deformed creature who was earning her living by making shirts, who came to me with those complaints, — illness and weakness, and all the rest of it, — and to whom I said, what was quite true, 'You want nothing but food.' I recollect the woman throwing out her hands and showing a few half-pence, hardly sufficient to cover her palms, and exclaiming, 'If that be so, how am I to get food?' I have spent hours in a den in which there was scarcely room to turn, attending to the sufferings of a woman who was about to add to a numerous family, the ordinary resting-place of whom was underneath the bed. . . . I left that scene to my great satisfaction, and some time after embarked on a voyage around the world, where I had an opportunity of seeing savage life in all conceivable conditions of savage degradation, and I can assure you in this experience of mine I found nothing worse, nothing more degrading, nothing so hopeless, nothing nearly so intolerably dull and miserable as the life I had left behind in the East End of London. For although the savage may perish of hunger or violence, and never knows whether his life may be his own twenty-four hours, yet there is life in him, he is a man, he is not a mere machine ground down to bring out so much mechanical energy at the expense of so much food; and I most certainly say that if the alternative were presented to me to choose between the life of one of those people in the East End or that of the savage, I would distinctly choose the latter."

[1] Since writing the above we find "herniated" in Dunglison, but are none the more inclined to retract our criticism.

Medical and Surgical Journal.

THURSDAY, JANUARY 10, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

NERVE STRETCHING.

THE second Bradshaw lecture was lately delivered before the College of Surgeons of England by its President, Mr. John Marshall, who chose for his subject Nerve Stretching for the Relief or Cure of Pain. The first of the lectures on this foundation, that by Sir James Paget, treated of new forms of disease, and the second, not inappropriately, discusses a new operation for the relief of disease.

The lecturer, himself an enthusiast in his subject, discusses it thoroughly from both the physiological and therapeutical stand-point. The obstinate character of the cases in which recourse is had to the operation (sciatica, locomotor ataxia) seems to justify almost any therapeutic measure which affords even a meagre prospect of relief, while the enthusiasm with which the operation has been taken up in various quarters shows that this prospect has been considered by many quite the reverse of meagre.

At the outset it was proposed not only to relieve the pains of locomotor ataxia, but to retard pathological processes in the spinal cord in such diseases by stretching the sciatic nerves. Wonderful cases of relief from ataxia were reported, but more extended study of cases seems to have shown that when the immediate effect of the operation has passed away the patient may be expected to relapse into his former condition with only a temporary relief of symptoms to repay him for the discomfort and risk attending the operation. Four consecutive cases in which the operation was thoroughly performed by Tiersch, of Leipzig, were reported in the JOURNAL (March 2, 1882) in which not only all the other symptoms of locomotor ataxia returned in full force after a certain period, but special note was made of the fact that after this period the pains were in no case in the least degree lessened. Such results as these have led various authorities to denounce the operation in unmeasured terms. Mr. Marshall takes quite the opposite view, and seems to regard the operation as worthy of a far greater degree of consideration than it at present enjoys. The probability of cure of sciatica he considers great, while the results in relieving the pains of locomotor ataxia he finds by no means discouraging.

In forming an opinion on theoretical grounds of the probable value of nerve stretching in these two affections the different character of the pains must be taken into consideration, and a general idea of the changes produced by the operation must be kept in mind.

In sciatica, as stated by Mr. Marshall, the pains arise probably from irritability of the small nerves which supply the sheath of the sciatic nerve. This explains the distribution of the pain along the course of the nerve, for if the source of irritation were in the sciatic nerve itself the pain would be referred to its extremities rather than along its course. In locomotor ataxia, on the other hand, the pains probably indicate merely the points to which are referred the effects of irritation of the posterior nerve roots in the spinal cord or where those nerve roots leave the cord.

After stretching alterations are visible both in the sheath of the nerve and in the nerve itself, the fibres of the former, for example, are straightened and compressed, while the nerve itself undergoes changes varying in degree according to the force employed, complete degeneration of the nerve elements following excessive stretching, to be succeeded later by regeneration. Motor and sensory functions are in this case modified, and disappear to return during the period of regeneration. Whether the spinal cord itself is materially affected by the operation is extremely doubtful, although Mr. Marshall seems to favor the idea of vaso-motor and trophic changes, and seriously suggests the desirability of stretching the nerve downward in disease of the cord, and upward in sciatica. Such changes must, however, be looked on as purely hypothetical, and it is not easy to see how stretching the sciatic nerve can produce lasting benefit in diseases of the spinal cord or even mitigate the pains accompanying those diseases. The irritation to nerve roots produced by degenerative changes at the spinal origin of the sciatic nerve can hardly be materially affected by stretching the nerve in its course through the thigh, unless, possibly, as a secondary effect of the powerful peripheral irritation. In point of fact the results of the operation in such cases up to the present time would hardly encourage a conservative surgeon to undertake the operation.

In regard to neuralgias the prospect seems somewhat more encouraging, both theoretically and judging by statistics. Many of the small nerves in the sheath of the sciatic must be so stretched by a forcible operation as to lose their functions permanently, and if the stretching is done so near the seat of pain as to destroy the nerves whose irritability causes the pain, a radical cure is by no means impossible. In point of fact the statistical results of the operations for sciatica, while open to the distrust attaching to all statistics of this sort, are so favorable as to justify reserving our opinion on this branch of the subject for the present.

There is a third class of cases in which Mr. Marshall considers nerve stretching indicated, namely, cases of painful ulcer, neuromata, and similar peripheral lesions. From this view we should on theoretical grounds decidedly dissent, for although the pain from such peripheral irritation may be lessened temporarily by destroying the conductibility of the nerve, there is no reason to assume that the relief from pain will remain permanent after the regenerative process has restored that conductibility.

One consideration, and by no means an unimportant one to the practitioner, seems to have been treated rather lightly by the lecturer; this is the *danger* of the operation. Nocht reports one death in twenty-four cases, even in sciatica, a fact by no means to be forgotten in prescribing the operation for a disease in itself not dangerous. As to the danger in diseases of the spinal cord, when we remember that the number of cases considered hardly reaches fifty, the conclusion drawn in the following sentences by Mr. Marshall seems rather startling: "With regard to the dangers of nerve stretching in tabes, if you read the cases, you will find that they are comparatively few. One patient died from chloroform, another from thrombosis in the veins, another from pyæmia due to inattention to antiseptic dressings, a fourth from a similar cause. Then we may record three or four cases in which, undoubtedly, the death may be attributed to disease of the spinal cord set up by nerve stretching, but one of these was a case of spasmodic disease. In other words, the peculiar dangers of the disease for which this operation is performed, superimposed upon the dangers to which all operations are liable, render the mortality so great as to offer a serious impediment to its adoption."

THE NATIONAL BOARD OF HEALTH. THE REPORT FOR THE YEAR 1882–1883.

THE Report of the National Board of Health for the year ending June 30, 1883, shows that of the $50,000 appropriated by Congress for aid to State and local boards of health the sum of $49,947.95 was spent in inspecting immigrants, to control the spread of smallpox, in maintaining the Mississippi River-Inspection Service and the refuge stations at Sapelo Sound and Hampton Roads until October 20, 1882, and the Ship Island Station until November 15th (to accommodate a late-arriving infected Austrian bark). Of $17,500 appropriated for the other expenses of the Board, a little less than $5000 remained unexpended at the end of the year. For the present year Congress has appropriated only $10,000 for all purposes.

The Board has since its creation done work of the greatest practical value, in stamping out yellow fever in New Orleans in 1879, and in restricting its ravages to Memphis in the same year, in establishing quarantine stations in case of cholera or yellow fever importation, in securing sanitary reports from our foreign consuls, in organizing a system of river, railroad, and general inland medical inspection, in restoring confidence where shot-gun quarantines had formerly prevailed, in securing useful legislation to control pestilences, and, most of all, in sanitary surveys and scientific investigations of the utmost importance.

The Board has had a splendid opportunity and it has done good work. For the last two years, however, there has been an evident lack of confidence in it at Washington, the direct result of which has been that Congress has placed in the hands of the President the large appropriation of $100,000 each year, to be used in controlling infectious disease; and the President, through the Secretary of the Treasury, has disappointed the National Board of Health by putting this money at the disposal of the Marine Hospital Service. The Board has apparently not been able to see, what has been so obvious to others, that this action has meant most decidedly that its exsitence in its present form is no longer desired. In any other country than the United States the resignation of its members would accordingly have been speedily placed in the President's hands.

The Board has had an exceedingly difficult task to perform. Most of it has been done thoroughly well. How some of it has been done may be inferred from the thirty pages out of one hundred and two of the report before us, devoted to the old quarrel with the Louisiana Board of Health, and which probably few people are interested to hear now. There may have been fault on both sides, but the issue is an old one and settled long ago.

If the matter of maritime inspection and control of vessels capable of bringing infectious diseases to our ports is left in the hands of the Marine Hospital Service, so far as it can be regulated by a central authority with the coöperation of the various local boards of health, there will be enough for a national health organization to do in supervision of vital statistics, in making sanitary surveys, in chemical analyses of food, air, water, in carrying out scientific investigations, in examinations of the causes of disease and special outbreaks of disease, in suggesting legislation to protect the public health, in advising local boards regarding the means for controlling epidemics, and, if necessary, establishing inspection stations under their own supervision and control, working in harmony with the Marine Hospital Service and State and local boards, in cases where the interests of several States might seem to conflict, or where coöperation is needed.

In that case, the basis of representation of the Board should be very much widened, the members should include other occupations and interests than the medical, annual meetings would probably be sufficient, and some sort of an executive board should be permanently employed in Washington, with duties similar to those of the already established sanitary bureaus of England, France, Italy, and Germany.

THE MASSACHUSETTS BOARD OF HEALTH.

THE part of the inaugural address of his excellency Governor Robinson which refers to the Board of Health, Lunacy, and Charity is of considerable interest to the medical profession of Massachusetts, and, in so far as her old Board of Health was a model for others in various parts of the country, anything affecting it concerns a wider audience.

We cannot, in speaking for the medical profession, express disappointment or surprise that the Governor should not have seen his way clear to recommending at the present moment a division of the present complex organization, nor do we desire to urge a measure, however desirable in the abstract, out of season as

well as in season. But, whilst realizing perfectly by what a variety of considerations political action is and must be controlled, we should be very much disappointed, and in this we believe we express the sentiments of a large and influential part of the profession, should next year's Governor not recommend changes neither "radical nor sweeping," which to this year's Governor seem injudicious.

In the mean time it is unnecessary to scrutinize or criticise his excellency's remarks, which appear in another column, too closely. If not spirited they are at least eminently prudent. Exception might be taken to the expression "a thorough reorganization of the administration of the public charities as accomplished by the Legislature of 1879," and to the statement that "a considerable saving was effected in the operation of the official machinery." Neither is it "plain" that the division of the present conjoined Board, whose name is typical of its cumbrous and vicious organization, would necessitate payment of additional salaries and outlay. No saving has been effected by the union of the Board of Health, nor would additional expense be incurred — even in the supervision of small-pox — by its separation. Good work can be done by the present organization under the most favorable conditions, but better work could and would be done — certainly in the department of health — by a separate board than by a sub-committee.

The one change which his excellency does suggest, and that in the form of a query, relates to a union in the administration of charities of the departments for in-door and out-door poor. Such a change it is, we believe, entirely within the province of the Board of Health, Lunacy, and Charity to effect without action on the part of the Legislature; and, in fact, the action of the Board at its last meeting, only two days after the inauguration, in accepting the resignation of the Superintendent of Out-door Poor, to take effect February 1st, would indicate that such a change had been for some time contemplated.

Health and an unincumbered organization for its supervision are among the most important interests of a State, but it is also true — and this as professional men we may have a tendency at times to forget — they are not the only ones. Another year, it is to be hoped, will make a restoration of a separate Board of Health possible. In the mean time we may heartily reiterate Governor Robinson's, to us not unfamiliar, protest against the introduction of politics, and we may add of personalities, into these questions of charities and sanitation.

THE PRIZE OFFER BY THE WORSHIPFUL COMPANY OF GROCERS, LONDON.

WE have made room in this issue of the JOURNAL for the announcement of the offer and the conditions of the first quadrennial Discovery Prize of £1000 for original research in sanitary science, emanating from the Worshipful Company of Grocers in London. The document is dated May 30, 1883, and seems to be a little slow in circulating; the offer of the prize was referred to in our columns as long ago as last August. The subject proposed — the discovery of a method by which the Vaccine Contagium may be cultivated apart from the animal body, in some medium or media not otherwise zymotic — is well chosen and should excite competition, being directly in the fashionable line of scientific research of the day. Such a discovery to silence the clamor of popular prejudice, we imagine, is even more to be wished in a country like England, where animal virus is less used, than with us. But the discovery and the process of teaching it would be welcome everywhere.

The name of the Company of Grocers associating itself with the advancement of original research in sanitary science suggests some curious reflections. This fraternity was originally denominated the "Pepperers," and was incorporated under its present name in the reign of Edward III. The Livery Companies of London were originally incorporated to benefit trade, to train artisans, to repress bad workmanship, and to exercise benevolence, especially to members of the guilds and their families, of which functions they are represented as performing none at the present time. The Grocers' Company in 1450 obtained the office of "garbeller of spices," which gradually entailed a supervision of the adulteration of food and drugs, with power of prosecution, and the City records show at different periods that these duties were performed very energetically. In 1664, the physicians having obtained a charter of incorporation which seemed likely to abridge the sphere of the company's medical control, the following notice, according to Herbert, appears on their books: Divers members of this company trading in drugs made request and suit for the countenance of the courts in the freedom of their trade, against the invasion of the College of Physicians, who, having lately obtained from his Majesty a patent, with new and strange power of privilege and search, seizure, fine, and imprisonment, are attempting the passing of a bill in Parliament for the ratification of the same, which, if effected, will be an insupportable inconvenience and prejudice.

Among other curious duties of the Grocers was that of deputing two of their fraternity to stand all day with two of the Ironmongers at Bishopsgate to see that no citizen passed through wearing any dress that his position did not entitle him to wear. Herbert's "City Companies" and Gilbert's "The City" give many details of the development of the London Livery Companies which would be interesting to the historically inquisitive.

Within late years the pressure of public opinion has constrained some of the most wealthy of these companies, of which the Grocers is one, to devote a portion of their enormous revenues to other purposes than feasting, and the present prize offer is one indication of good results from much agitation of the great abuses attaching to the administration of these revenues. It was estimated that the Goldsmiths' Company alone expended for feasting during one year in their hall the sum of £30,000, and the total average annual expenditure of all the Livery Companies, with the

accessories of their halls, etc., for feasting was stated, in 1876, at no less a sum than £150,000.

A quadrennial £1000 withdrawn from such an amount, though seeming like a large prize to sanitary science, is but a small alleviation to the burden under which the livers of these livery men labor. It should, indeed, as far as it goes, be twice blessed.

MEDICAL NOTES.

— We understand that Messrs. Weeks and Potter, prominent wholesale druggists, have withdrawn their appeal, and paid their fine in the suit brought against them by the Massachusetts State Board of Health for selling laudanum of inferior strength.

— A new out-patient building at the Massachusetts General Hospital, in memory of the late Dr. George H. Gay, for years a member of the surgical staff of that hospital, was opened January 1st. We shall publish a fuller account of it.

— W. Brewster Platt, M. D., of Baltimore, a graduate of the Harvard Medical School a few years ago, was last month admitted a Fellow of the Royal College of Surgeons, England.

— The Cartwright Lectures for 1884 will be delivered by Prof. Burt G. Wilder, M. D., of Cornell University, at the hall of the Young Men's Christian Association, corner of Twenty-Third Street and Fourth Avenue, New York, on the evenings of February 2, 4, and 6, 1884. The general subject will be Methods of Studying the Brain.

— The following are the lecture arrangements at the London College of Physicians for 1884: The Gulstonian Lectures will be delivered by Dr. Clifford Allbutt on March 7th, 12th, 14th, the subject being Chapters on Visceral Neuroses. The Croonian Lectures will be delivered by Dr. Hughlings-Jackson, on March 19th, 21st, 26th; subject, Evolution and Dissolution of the Nervous System. And the Lumleian Lectures by Dr. James Andrew, March 28th, April 2d, 4th; subject, The Ætiology of Phthisis.

— *Virchow's Archiv* for December contains a summary, by Dr. Uhde, of Braunschweig, of the examinations of pork for trichinæ in the Duchy of Brunswick. The total number of carcasses of swine examined was 120,766. Of these eleven were found to contain trichinæ, and 109 were otherwise diseased.

— The statue of Liebig, at Munich, has been mutilated by the pouring over the entire left side of the figure of some dark-colored liquid, which has corroded the marble. The perpetrators of the outrage have not been discovered.

— Chloroform water, which is much employed in the Paris hospitals, is prepared as follows, says *L'Union Médical* (November 22d), according to Professors Lasègue and Regnauld's formula: An excess of chloroform is poured into a bottle three parts filled with distilled water, and, after repeated shaking, the mixture is allowed to stand until the extra chloroform is deposited, and the liquid quite clear. The transparent portion is then to be removed by a siphon, forming a saturated solution of ten grammes of chloroform per litre. Applied on compresses, either in its pure state or diluted with a half or its whole weight of water, it is found to relieve superficial pains; but when these are more deeply situated, a very hot linseed-meal poultice is first applied, which is afterwards replaced by the compress of chloroform water. Active revulsion is thus produced, which relieves the pain. Associated with a weak solution of opium it relieves vague dental pain; and with syrup of morphia it is successfully given internally for various forms of malaise from indigestion, such as gapings, eructations, sense of weight, etc. It is also useful as a palliative in cancer of the stomach.

— Dr. Sedan (*Gazette des Hôpitaux*, September 15th) reports the case of a young man, nineteen years of age, who for nine years was in the habit of taking daily between one hundred and one thousand grammes of ether. When first seen by Dr. Sedan, at ten years of age, he had anæmia, with a souffle accompanying the first sound of the heart, but preserved nevertheless a very satisfactory general condition. He became one of the most promising students of the Lyceum, was quick, brilliant, intelligent, laborious, and successful. He confided to Dr. Sedan that he drank ether, and that was the secret of his success; he reasoned like a man, and promised not to use the stimulant except to assist the efforts of his intelligence. From that time he commenced increasing amounts of ether, twenty to thirty, fifty, eighty, one hundred grammes a day, and as much at night in vapor. Still he was at the same time engaged in working out the most difficult questions in the higher mathmatics. Neither parental authority nor medical advice availed to break him of the habit. He finally consumed nine hundred to one thousand grammes a day, mostly by the mouth. He was undersized, and with a feeble constitution. No immediate disturbance showed itself at first, and he finally died of mitral insufficiency. During the last year of his life he used both ether and morphia subcutaneously.

— The English census reports show that the proportion of the blind to the population has not only decreased with each successive enumeration since 1851, in which year account of them was taken for the first time, but the decrease in the decade ending in 1881 was much greater than in either of the preceding intervals. The number of cases in 1881 was 22,832, which was one blind person in every 1138.

NEW YORK.

— At the first meeting of the Academy of Medicine in the new year, held January 3d, the following officers, all New Code men, were elected: Vice-President, Dr. Robert F. Weir; Member of the Board of Trustees, Dr. Cornelius R. Agnew; Treasurer of the Board of Trustees, Dr. Frederick A. Castle; Member of the Committee on Admission, Dr. Daniel Lewis; Member of the Committee on Ethics, Dr. C. Dixon Tarley; Member of the Committee on Education, Dr. W. Gill Wylie; Member of the Committee on Library, Dr. Abram Jacobi. At the same meeting a very fine life-size portrait of the late Dr. James R. Wood,

painted by Mr. Thomas Hicks, was presented to the Academy by Dr. F. H. Bosworth, on behalf of a number of old office students of the deceased surgeon. This was followed by a memoir of Dr. Wood, by Dr. Frederick S. Dennis, after which Dr. Thomas Addis Emmet read a memoir of Dr. J. Marion Sims. The annual reports of the treasurer, the board of trustees, the treasurer of the board of trustees, the recording, corresponding, and statistical secretaries, and of the various standing committees were also read either in full or constructively by title. From them the following items of interest are taken: The receipts of the Academy for the year just closed were $4,249.57, and the disbursements $4,429.78. During the year seven resident Fellows, one non-resident Fellow, and one honorary Fellow have died, and there has been one resignation of membership. Twenty new resident Fellows have been elected. The roll of the Academy now shows 380 resident Fellows, eighteen non-resident Fellows, forty-three corresponding Fellows, and six honorary Fellows. The number of visitors during the year was 4699, and there were received 721 bound volumes, 1839 pamphlets, and 7349 copies of medical journals. The estimates of the expenses of the library for the ensuing year were as follows: for salaries $1212; journals, $650; incidental expenses, $138; total, $2000.

— The Attorney-General has begun a suit in the Supreme Court against the Eclectic Medical College of New York for the annulment of its charter and the dissolution of the corporation controlling it, on the ground that the college has been issuing diplomas in blank, and has sold them to incompetent persons who have filled them in with their own names. The County Medical Society, through its counsel, Edward C. Ripley, Esq., has been engaged since last April in tracing the history of certain diplomas issued by this college, and it is stated that the facts show that the plan of granting diplomas is as unscrupulous as that exposed and put a stop to in the American University of Philadelphia.

— The "New York Anthropological Society" was organized December 28th, with the Rev. Dr. E. P. Thwing as president, Dr. R. Ormiston vice-president, and Dr. A. D. Rockwell, secretary.

— At their last meeting the Aqueduct Commissioners decided to construct the new aqueduct of the size of fourteen feet internal diameter, and that its northern terminus should be at the present Croton dam. The construction of the Quaker Bridge dam, which is designed to form a reservoir capable of holding 32,000,000,000 gallons of water, has not yet been definitely determined upon.

— The amount of the collections on Hospital Saturday and Sunday has not yet been announced; but, on account of the more complete and extended organization of the movement this year, it is supposed that it will be largely in excess of the sum contributed in 1882. The "Hymn for Hospital Sunday," composed by a clergyman, was sung in a number of churches on the 30th of December.

— Dr. E. Darwin Hudson has been appointed a visiting physician to Bellevue Hospital.

Correspondence.

HOSPITAL ABSENTEEISM.

MR. EDITOR, — I have read with interest the communication in your journal signed "Nestor," on the subject of medical absentment from hospital duties; and while I agree in the main with the principles therein expressed, yet I think there is another side of the question which deserves consideration. I too have done my full share of hospital work, and while I have fully appreciated the honor and responsibility of a position on the staff of a public medical institution, yet have I never failed to take a reasonable respite from my work at some period of my term of service, not only for the sake of rest, but also to afford my juniors in the out-patient department opportunities of becoming familiar with duties which some day must devolve upon them.

I fail to see that dignity or duty suffer any detriment from my so doing. A fortnight's vacation during one's term of service, on the contrary, is a distinct benefit in more ways than one; and I venture with all due respect to assert that had "Nestor" pursued this course, his own health would have been better, and that of his patients no worse. SENEX.

HOSPITAL ABSENTEEISM.

MR. EDITOR, — Can you pardon the follies of youth? If so, extend your clemency to me, for I have yielded to the temptation to burst into song, and express "Nestor's" sentiments on the subject of medical absentees in poetic patter. Should my effort find admirers, please inform them that I am willing to exchange the copyright of my song for an engraving or colored print (composition of subject must include at least one cadaver) for office or waiting-room decoration.

THE SONG OF THE ABSENTEES.

Let others auscult or percuss,
Examine all sorts of secretions
Of ill-smelling patients who fuss,
Prescribe building-up and depletions.

Let others work hard and perspire,
Pant, struggle, e'en fall in the race,
While we pack our traps and retire,
Assured in advance of a place.

While we roam the hills or the waters,
Intent upon pleasure or gain,
Let them stay the slaughter of paupers
Who in the hot city remain.

To them be the privilege given
Of hospital work without stint;
Let them lay up riches in heaven,
But give us the credit in print!

GAMBOGE.

SEA-WATER FOR STREETS, SALT ON STREET RAILWAYS.

BOSTON, *January* 3, 1884.

MR. EDITOR, — Can you tell us what there is "*injurious to health*" in watering streets with sea-water, or in putting salt on street railway tracks? By rapid thawing of snow or ice there may be produced too great cold perhaps for horses' feet, which, however, do not ordinarily come very near the rails; or possibly the salted water may be irritating to sore or tender

hoofs. But if such be the case, what has it to do with "the public health?" How can the public health be injured by watering streets with sea-water in summer, when all are urged to dip themselves into the ocean itself for health's sake; or by the running off into drains and cesspools in winter of salted ice-water slightly ferrated by the iron rails of the railway?

One would naturally think these things innocent; and yet they have frequent denunciations from Boards of Health; and courts are besieged to put a stop to such proceedings.

Please, Mr. Editor, enlighten on these points frequent inquirers and NESCIENS.

DOWNWARD DISPLACEMENT OF THE TRANSVERSE COLON.

MR. EDITOR, — Dr. Thomas will find, in Bright on Abdominal Tumors, Sydenham's Society's edition, pages 247–250, some remarks on displacement of the transverse colon, with a diagram of a case (Fig. 67), exactly like those reported by him. Esquirol, Maladies Mentales, Paris, 1838, tome i., page 462, speaking of the same lesion in insanity, says: "Quelquefois le colon transverse descend en forme d'arc au dessous du pubis et jusque dans la cavité pelvienne." Both authors give cases of the various other forms of displacement, but not of the particular U-shaped variety here spoken of. I have had no time to look into the subject any farther, but think the references above given must show that it is by no means so rare as the Philadelphia gentlemen seem to suppose.

Yours respectfully,
EDWARD T. WILLIAMS, M. D.

January 4, 1884.

Miscellany.

GOVERNOR ROBINSON'S INAUGURAL.

HEALTH, LUNACY, AND CHARITY.

THE following is the portion of his excellency Governor Robinson's inaugural address relating to the above important subjects: —

The Legislature of 1879 accomplished a thorough reorganization of the administration of the public charities, — abolishing some boards, consolidating others, and simplifying the whole system. Undoubtedly a considerable saving in the operation of the official machinery was effected. The Board of Health, Lunacy, and Charity, as then and now constituted, consisting of nine persons, is given general supervision over the State lunatic hospitals, the State Almshouse, the State Workhouse, the State Primary School, the State Reform School, and the State Industrial School. Other powers, ample and specific, are granted, enabling the Board to hold substantial control over those institutions and over other matters committed to it. The Board also takes cognizance of the interests of health and life among the citizens of the Commonwealth, and acts as Commissioners of Lunacy. Surely no board in this State ever was intrusted with graver concerns and heavier responsibilities. I am sure that most faithful, disinterested, and efficient service, without a dollar of compensation, has been rendered by the members of that Board, and they are fairly entitled to the appreciation and gratitude of the citizens of the State and, most of all, of the poor unfortunates whom the charities of Massachusetts support and save.

The consolidation effected in 1879 was not brought about without opposition from very wise and devoted persons, many of whom, if not all, still believe that no satisfactory work can be done until a separation is made, and there are three boards or commissions instead of one. There is an apparent incongruity in the present arrangement, it is true; but in many particulars the three branches are closely allied, and may be harmoniously and effectively worked together. It is not possible that each member on such a board can be an expert in all the matters before it. They must make investigations and reach results through subcommittees; and yet it is quite common in public affairs to manage important interests in just this way. I have been urged to recommend to you an abolition of the Board, and the creation of two or three in its stead. But after much reflection and extended inquiry I must withhold that recommendation for the present. It is plain that the adoption of the suggested plan would necessitate payment of additional salaries and other outlay. Though there is much in the propositions that I approve, still I am persuaded that the people, whose servants we are, look with suspicion and disfavor upon the needless multiplication of boards, commissions, and agencies, and approve the practice of the strictest economy in their behalf. My own inclination at present would be toward a still further reduction and simplification that would bring all our public institutions more directly under the supervision of one board; but my experience and observation in the management of so great trusts will not, in my judgment, justify me in recommending radical and sweeping changes. Let the work of the Board be searchingly scrutinized, not only in its economical bearings, but as well in its response to the demands of humanity and justice. Political partisanship has no proper place in such an organization, or in the examination and estimate of its transactions. Whatever else we do, let us see to it that we keep politics out of the charities.

I am reënforced in the conclusions already stated, in the fact that unusual interest has been excited during the last year in the official acts of the Board, and in the conduct and condition of the various institutions under its charge; and the report of the Board, presenting their views and conclusions, will attract extraordinary attention. It is but justice that we consider it. Moreover, a joint special committee was created by your immediate predecessors to investigate several of the institutions; to consider plans and theories; to examine institutions in other States, and to present their findings and conclusions to you. Their report will undoubtedly give you valuable information and help. I desire to suggest that I fear there may be a tendency to an unnecessarily large force of clerks, agents, assistants, superintendents, and employees appointed by the Board under statute authority. May not the departments of the out-door poor and the in-door poor be united, saving the compensation of several persons, and in no degree impairing the efficiency of the service? If you agree with me, this retrenchment can be effected without difficulty. It is probable that other savings can be accomplished, and in that direction I shall turn my attention and now invite yours. I ask your attentive consideration to the several reports sub-

mitted by the boards of trustees. They speak from an abundant observation and experience.

LUNATIC HOSPITALS.

There is an imperative demand for increased accommodations for the insane. The hospitals are crowded, and hundreds of inmates are compelled to occupy temporary cots, or beds in the corridors and upon the floors. I believe great economy of room is possible under a wise system of classification, separating the harmless, the criminal, and the dangerous, and other improved arrangements which professional knowledge and practical experience will advise. Let us adopt any and every reasonable expedient before we enter upon the construction of another hospital, or incur large expense in experiments in one field or another to test a theory. The financial affairs of the hospitals are reported in excellent condition. The surplus accumulated at Taunton, Worcester, and Northampton has been increased; while at Danvers the treasurer's report shows a balance of $1172.14, so that the $10,000 appropriated for an anticipated deficiency has been added to the surplus.

MEETING OF BOARD OF HEALTH, LUNACY, AND CHARITY. RESIGNATION OF SUPERINTENDENT OF OUT-DOOR POOR.

DR. H. B. WHEELWRIGHT'S resignation as Superintendent of Out-door Poor was accepted, to take effect February 1st. Messrs. Fallon, Noble, Dean, Haggett, and Walcott voted to accept the resignation, although Dr. Wheelwright wished the term extended to April 1st. Meanwhile his department will be put in charge of the charity committee of the board. There was some animated discussion on this subject, but the result showed a large majority against the doctor. Ex-Governor Talbot intimated that those who wished to press this matter were active from personal spite. Colonel Haggett said he should throw the remark back in his face, and that he was not actuated by personal spite. Tewksbury has 1170 inmates, and will take no more at present. Miss E. C. Putnam was formally thanked for her efforts to reclaim wayward children by her plan of auxiliary visitors. Messrs. Talbot and Walcott were instructed to take advice of counsel as to having the State pay the Boston City Hospital for patients sent there.

THE CHILDREN'S HOSPITAL.

THE fifteenth annual meeting of the managers of the Children's Hospital was held in this city, in December, and the following officers were chosen for the ensuing year: President, Robert C. Winthrop; Vice-President, John C. Phillips; Treasurer, John G. Wetherell; Secretary, Francis H. Brown; Managers, Charles Faulkner, William Ingalls, Charles H. Fiske, Jeremiah Abbott, Alanson Bigelow, J. P. Spaulding, H. G. Pickering, Roland C. Lincoln, J. Montgomery Sears, Oliver W. Peabody, Phillips Brooks, Charles L. Young. The managers, in their annual report, say that the past year has been in many respects experimental in the management, care, and testing of the new building, and that they are well satisfied with the result. The entire cost of the building, including furniture and equipment, has been about $125,000. It is now wholly paid for. The hospital has now accommodations for sixty patients, which is double the number receivable in the house formerly occupied on Washington Street. Each of the two wards has twenty beds; there are five rooms for private patients, and three rooms designed for special cases, for those which need the quiet of a separate apartment. This year the aggregate of the house bills (as also the total cost of the maintenance of the hospital) has been double that of the previous year. This is due to the increase in the number of employees, and to the cost of their wards. The average daily number of children approximately in the former building was eighteen, and the annual expenses were, exclusive of rent, about $7500, making the daily cost for each patient about $1.14. In the present building the average has been thirty-seven patients per day, and the year's expenses have been $16,501.28, making the daily cost for each patient about $1.22. This record has been compared with those of similar institutions in Massachusetts, and the comparison is very favorable and satisfactory. The number of children received and treated in the wards during the year is 279, and the total number since the establishment of the hospital is 2033; in the out-patient department about 1000 in the last year. The report acknowledges aid received from the Ladies' Aid Association, the Sisters of St. Margaret, and others, and speaks appropriately of the deaths of Nathaniel Thayer, formerly president, and of Isaac Thatcher.

SURGEON-GENERAL HOLT.

DR. A. F. HOLT, of Cambridge, has been appointed Surgeon-general on the staff of Governor Robinson, and has accepted the position. Dr. Holt was graduated in medicine at the University of Vermont in 1860, and enlisted in April, 1861, as a private in a Cambridge company, for which the claim is made that it was the first raised, and which became Company C of the Third Volunteer Regiment. Returning home at the end of his three months' service he was made assistant surgeon of the Thirtieth Massachusetts Regiment. A year later he was surgeon of the First Texas Cavalry, then major and lieutenant-colonel of that organization, of which he was in actual command at the close of the war. His military career was distinguished for bravery and he was made the subject of a complimentary general order from the Department of the Gulf for his courage in bearing away the wounded from under fire. Since the war Dr. Holt has been engaged in general medical practice in Cambridge, where he has filled the office of City Physician. He has been medical examiner since 1879, receiving his commission from Governor Talbot. We understand that his excellency has chosen to make appointments to his personal staff from those who saw actual service during the war, and in his selection of Dr. Holt he has a surgeon-general who by personal and professional qualities will ably fill and adorn the honorable position.

— A correspondent of the *New York Medical Journal*, December 29th, narrates the case of a young man in whose rectum a hard, green pear, measuring three and a half inches by two, had been placed by companions while he was in a state of intoxication. It was removed by lithotomy forceps (the patient being in Sims' position) with some hæmorrhage and temporary paralysis of the sphincter ani.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 29, 1883.

Deaths reported 2725 (no reports from District of Columbia and New Haven): under five years of age, 939: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 543, consumption 419, lung diseases 400, diphtheria and croup 226, typhoid fever 70, scarlet fever 67, diarrhœal diseases 52, measles 35, malarial fever 35, cerebro-spinal meningitis 16, erysipelas 14, whooping-cough 12, puerperal fever 10, small-pox six. From *diarrhœal diseases*, New York 18, New Orleans nine, Boston seven, St. Louis four, Baltimore, Cincinnati, Charleston, and Fall River two each, Philadelphia, Brooklyn, Chicago, Lowell, Cambridge, and Taunton one each. From *measles*, Baltimore 16, New York five, Philadelphia four, Brooklyn three, Buffalo two, Chicago, New Orleans, Pittsburg, Milwaukee, and Lowell one each. From *malarial fevers*, New Orleans 12, New York seven, Baltimore five, Brooklyn four, Chicago three, St. Louis two, Charleston and Nashville one each. From *cerebro-spinal meningitis*, Fall River three, New York, Cincinnati, and Springfield two each, Philadelphia, Milwaukee, Charleston, Nashville, Lowell, Salem, and Taunton, one each. From *erysipelas*, New York eight, Philadelphia and Boston two each, Cincinnati and New Orleans one each. From *whooping-cough*, Boston three, New York, Philadelphia, and Baltimore two each, Brooklyn, Chicago, and New Orleans one each. From *puerperal fever*, Chicago three, Philadelphia, Boston, Buffalo, Milwaukee, Providence, Charleston, and Springfield one each. From *small-pox*, Philadelphia four, New Orleans two.

Seven cases of small-pox were reported in St. Louis; diphtheria 26, scarlet fever 25, and typhoid fever 10 in Boston; scarlet fever 17, and diphtheria six in Milwaukee.

In the 79 cities and towns of Massachusetts, with an estimated population of 1,170,947 (estimated population of the State 1,922,530), the total death-rate for the week was 21.05 against 18.60 and 21.60 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending December 15th, the death-rate was 22.6. Deaths reported 3735: acute diseases of the respiratory organs (London) 471, measles 125, scarlet fever 105, whooping-cough 80, fever 59, diphtheria 40, diarrhœa 33, small-pox (London seven, Birmingham, Liverpool, and Sunderland two each) 13. The death-rates ranged from 13.9 in Portsmouth to 29.2 in Manchester; Bradford 16.1; Leicester 20.5; Sunderland 20.7; Sheffield 21; London 22.7; Nottingham 23.6; Birmingham 24.3; Leeds 25.1; Liverpool 25.3. In Edinburgh 20.8; Glasgow 26.3; Dublin 32.1.

For the week ending December 8th, in 170 German cities and towns, with an estimated population of 8,725,681, the death-rate was 23.4. Deaths reported 3922; under five years of age, 1711; consumption 563, lung diseases 465, diphtheria and croup 281, diarrhœal diseases 124, scarlet fever 92, measles and rötheln 68, whooping-cough 52, typhoid fever 48, puerperal fever 19. The death-rates ranged from 30.5 in Dortmund to 14.1 in Kassel; Königsberg 29.1; Breslau 26.9; Munich 27.3; Dresden 26.5; Berlin 25.2; Leipzig 24; Hamburg 23.5; Cologne 22; Frankfort a. M. 16.0; Strasburg 25.4.

For the week ending December 8th, in the Swiss towns, there were 27 deaths from lung diseases, consumption 22, diarrhœal diseases 17, whooping cough four, diphtheria and croup two, typhoid fever two, puerperal fever one. The death-rates were, Geneva 13.3; Zurich 12; Basle 17.5; Berne 27.1.

The meteorological record for the week ending December 29th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date. Dec., 1883.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

THE WORSHIPFUL COMPANY OF GROCERS, LONDON. ORIGINAL RESEARCH IN SANITARY SCIENCE.

FIRST QUADRENNIAL DISCOVERY-PRIZE OF £1000. 1883–1886.

SUBJECT to the conditions of the Company's scheme, the Court now announces, as the matter of competition for this Prize, the following Problem: —

"To discover a method by which the Vaccine Contagium may be cultivated apart from the animal body, in some medium or media not otherwise zymotic, — the method to be such that the Contagium may by means of it be multiplied to an indefinite extent in successive generations, and that the product after any number of such generations shall (so far as can within the time be tested) prove itself of identical potency with standard Vaccine Lymph."

The Prize is open to universal competition, British and Foreign. Competitors for the Prize must submit their respective Treatises on or before the 31st of December, 1886; and the award will be made as soon afterwards as the circumstances of the competition shall permit, not later than the month of May, 1887. In relation to the Discovery-Prize, as in relation to other parts of the Company's Scheme in aid of Sanitary Science, the Court acts with the advice of a scientific Committee, which at present consists of the following members: John Simon, C. B., F. R. S.; John Tyndall, F. R. S.; John Burdon Sanderson, M. D., F. R. S.; and George Buchanan, M. D., F. R. S. All communications on the subject are to be addressed to the Clerk of the Grocer's Company, Grocers' Hall, London, E. C.

GROCER'S HALL, *May* 30, 1883.

For the Conditions of Candidature and Award, see underneath.

QUADRENNIAL DISCOVERY PRIZES IN SANITARY SCIENCE.

Purpose of the Foundation. — (1.) The Quadrennial Discovery-Prize of £1000 is intended to reward original investigations which shall have resulted in important additions to exact knowledge in particular, previously defined, sections of sanitary subject-matter.

(2.) During the pleasure of the Court, the Court will, once in four years, propose some subject for investigation; and a period of at least three and a half years will on each occasion be allowed for the investigation of the subject that has been proposed.

(3.) In determining, on each occasion, what particular subject shall be proposed for the Prize, careful regard will be had to all the scientific circumstances of the time; both as the urgency of existing needs for particular kinds of knowledge, and as to the expectations which may reasonably be held that discovery in the needed kinds of knowledge can be made within the allowed period.

Candidature for the Prize. — (4.) The Discovery-Prize will be open to universal competition, British and Foreign.

(5.) The period allowed for the competition will begin with the day of announcement of the subject for investigation, and will end with the last day of the fourth following December.

(6.) Any person who desires to be regarded as a candidate for the Prize must deliver, or cause to be delivered, at the Hall of the Company, within the allowed period, a letter in which he declares himself to be a candidate for the Prize, and the treatise on which he bases his candidature; such letter, and such treatise, to be addressed to the Clerk of the Company, who will give a dated receipt for the same. The competition-treatise of a candidate may, if the candidate so prefer, be delivered in successive parts, each bearing its proper date.

(7.) Each treatise in competition for the Discovery-Prize must be an original work by the candidate who sends it in. It may be a treatise which he has published at any time within the allowed period, or may be a treatise which he has not previously published.

(8.) Although candidature is not restricted to any one nationality, all treatises, and all communications with the Company in relation to them, must be in the English language. Translations into English of competition treatises published (within the allowed period) in a foreign language will be received on a like footing with treatises originally in English.

(9.) All treatises must be in print.

(10.) Each treatise must bear the name of its author.

(11.) Any particular candidate may be required to demonstrate practically to the Court, or to persons acting on their behalf, any fact or result which he claims to have discovered.

(12.) Candidature will be held to imply that the candidate undertakes to accept as regards himself the award which the Court shall make.

Award of the Prize. — (13.) The Discovery-Prize being intended to promote the fullest possible elucidation of the given subject, the respective merits of candidates will be rated by that standard; and, if the Court be advised that the most meritorious candidate has produced an original solution of the main scientific problem or problems involved in the matter of the competition, the Court will award to him the entire Prize.

(14.) Should the Court be advised that no candidate has solved the main scientific problem or problems, but that valuable progress towards the object has been made by one or more of the candidates, or that collateral discovery valuable to sanitary science has been incidentally made by some candidate in his prosecution of the main research, the Court will apply such portion of the Prize as they may see fit in recognition of merits thus brought to their notice.

(15.) In estimating the originality of treatises, the Court will have regard not only to the state of knowledge which existed at the time when the subject for investigation was announced, but also to such later advances of knowledge as may have been made up to the time when the treatises were sent in.

(16.) Where two or more candidates equally claim to have made discovery in the subject-matter of the Prize, further information may be required of them in support of their respective claims, and the Court will judge between the claims as they shall think right. Each candidate will have been at liberty to notify to the Court at his own time any discovery which he believes himself to have made. — See above, § 6.

(17.) Neither the Prize, nor any portion of it, will be awardable to any person who has not formally declared himself a candidate for the Prize. — See above, § 6.

(18.) The awarding or withholding of the Discovery-Prize is to be entirely in the discretion of the Court, and the Company is not to be under any legal responsibility with regard to the same.

CASES OF LESION OF THE BRAIN CORTEX ATTENDED WITH UNILATERAL SYMPTOMS.

BY S. G. WEBBER, M. D., BOSTON.

CASE I. GASTRALGIA; SYMPTOMS OF CEREBRAL LESION FOLLOWING VOMITING; UNILATERAL SPASM; MENINGEAL HÆMORRHAGE.

In February I was asked to see Mrs. W., a friend of one of my patients. She seemed to be suffering from a slight "cold," and was soon better, but remained rather weak. March 9th I saw her again. She was then suffering from an eruption which resembled in some respects urticaria, a local swelling of the skin, slightly red, which itched and smarted. There had been disturbance of the stomach for a few days previous, but not sufficient to attract much notice, simply a sense of distention and flatulence. The eruption soon disappeared, and later reappeared; the gastric distress was temporarily relieved, but two days later she had much trouble with wind in the stomach; the temperature was 100.4° F., the pulse 102; there was also nausea and an aversion to food. The distress from flatulence was not constant, but recurred at intervals, and continued several hours; sometimes the ingestion of food seemed to give rise to an attack. These were relieved by spirits of chloroform, and by careful feeding with milk, lime-water, and a very small amount of brandy, she gained steadily, and by the 17th was receiving about two quarts of milk in twenty-four hours. On the 17th there was an attack of flatulence, during which she strained hard to raise the gas, and had a pain on the right, just below the breast.

From the 18th to 22d the right side and back, to right of the spine, were the seat of most distress; occasionally the flatulence gave trouble. There was tenderness at first just below the right breast, then over the lower edge of the ribs, finally below the ribs, near the spine. All motions of the body were painful. Physical examination of the lungs showed nothing abnormal. The urine was normal. Once after taking tincture of aconite on account of dryness of skin and slight elevation of temperature the pulse became irregular. The amount of food taken at this time was very small. The pulse ranged from 96 to 120. The temperature was about 100° F., once ran up to 102° F. She was fed by enema, an egg beaten up with pepsin being given every four to six hours.

From the 20th till her death Dr. Mack, of Salem, her family physician, saw her nearly every day, and made valuable suggestions in regard to treatment.

The pain in the side was diminishing, and the amount of morphia was decreased. She seemed to be gaining. On March 22d, while straining in vomiting, she felt a sharp, severe pain in her neck and head. This was followed by very severe headache and an unwillingness to move the head, and later an attempt to move the head gave rise to expressions of pain, and every passive motion of the head was resisted.

From the 22d to 28th there was a gradual failure. Intelligence gradually diminished; she lay without speaking unless spoken to, and then answered very briefly; at length there was almost no response to questions, but she seemed to know her daughter; she moved her hands, drew up both legs or straightened them out at will, evidently suffered from distress in her head, slept only for a short time without waking, took a larger amount of food, had a temperature generally below 100° F., but in the evening of the 27th it was 102° F.; pulse about 90 to 96; respiration 22 to 30.

On the 28th she showed almost no sign of consciousness, would swallow liquids which were placed in her mouth, but seemed unable to swallow solid food. It was necessary to catheterize her. During the morning visit the left pupil was larger than the right; both responded to light. Respiration was occasionally interfered with; in the afternoon it ceased for a few seconds, and she became cyanotic. At six P. M. pulse was 120; temperature 102° F.; respiration 40. At eight P. M. she had had three spasms, and had a fourth during the visit. Both eyes were open and in constant vibratory motion; the face, especially the left side, was contorted; both eyes turned towards the left in extreme conjugate deviation; she raised the right hand, trembling, towards the head. The left hand and leg did not move sufficiently to disturb the bedclothes if at all. The spasm continued less than a minute. After it was over the left hand and leg were found to be completely paralyzed. There was no reflex action on irritating the skin of hand or foot, though on the right reflex action was perfect. Pulse was 120; respiration 40; temperature was not taken.

From this time the spasms were more or less frequent until the twelve hours preceding death, when there were none. After many of the spasms respiration ceased for one minute or longer, and the skin became very cyanotic. There was no gesture showing any sensibility excepting once when the position of the head was changed, she groaned and put her right hand to her head, and once when a subcutaneous injection was administered in the right arm she made a motion showing that she felt the prick. The convulsions underwent a slight change, the left hand and arm were more agitated, the right less. I saw one which began with opening the eyes; rapid convulsive agitation of the lids, of the left side of face and left arm, and to a less degree of the left leg; the whole body was moved, both eyes turned to the left as far as was possible, the head was not turned, the right side was much less agitated than the left. When the spasm ceased both eyes returned to the right and respiration ceased for nearly a minute, the skin became deeply cyanotic, and after breathing was reëstablished the dark color faded out very slowly. The pulse varied from 100 to 120; the respiration between the convulsions was about 36; the temperature when taken on several occasions varied little from 100° F.

Death occurred quietly on the morning of March 31st.

The autopsy was made two hours post mortem. There was a very abundant development of adipose. The heart was small; there were three or four small rough nodules on the mitral valve, not recent; the lungs were healthy, a few small ecchymoses under the pleura. Stomach, many small ecchymoses in the mucous membrane. Liver, spleen, intestines, normal; a medium-sized calculus in the pelvis of the right kidney.

The skull was of normal thickness, no undue adhesion of dura mater. Under the dura mater, between that and the pia mater on the right side over most of the posterior two thirds of the right hemisphere, was a

[1] Read before the Boston Society for Medical Observation, November 5, 1883.

clot of blood (Fig. 1); this did not reach quite to the vertex, extended into the middle fossa at the base, reached as far forward as the posterior extremities of the second and third frontal convolutions, as far back as the perpendicular fissure above, and extended under the occipital lobe below, but not to its posterior extremity.

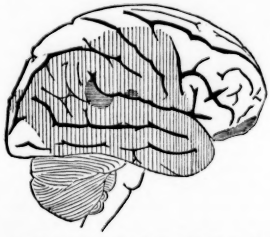

FIG. 1. Horizontal shading below fissure of Sylvius shows location of hæmorrhage; above fissure of Sylvius, the small spot of softening; perpendicular shading shows extent of meningeal hæmorrhage.

The first frontal convolution and the upper part of the superior parietal lobule were not covered by the clot.

The origin of the hæmorrhage was in the posterior and external part of the temporal lobe, near the point at which the supra-marginal gyrus merges into the first temporal convolution; this region was torn up by the blood which had broken through near the posterior extremity of the fissure of Sylvius so as to give rise to the meningeal hæmorrhage. The cerebral substance around the primary clot was softened and discolored to a limited extent, but the clot was firm, about the size of a walnut, and had undergone almost no change. On the upper side of the fissure of Sylvius in the anterior part of the supra-marginal gyrus was a small spot of softening, but no hæmorrhage. No blood was found in the ventricles.

The vessels, both arteries and veins, in the membranes were filled with firm dark coagula. The veins on the right side were very full. The arteries at the base were small, with extremely thin, delicate walls; no atheroma.

The ganglia at the base were healthy; in the white substance on the right side were several spots of punctiform hæmorrhages; one small spot, very superficial, was also noted near the acoustic striæ in the floor of the fourth ventricle.

No miliary aneurisms could be discovered with the naked eye.

This case is of interest in several particulars. The pain in the right side and back during a part of the time may well have been caused by the calculus in the pelvis of the right kidney, displaced perhaps by severe straining during an attack of flatulence.

At first I could discover nothing but acute gastralgia or dyspepsia. I examined carefully with a view of discovering some other condition of ill health, but could not; a decided improvement led to an expectation that the patient would recover until the attack of vomiting on the 22d, which was followed by the severe pain in the head. It was by no means easy to decide where or how severe the mischief was, there was no paralysis, there were no cerebral symptoms excepting the pain and the rather rapid loss of mental power. The patient was naturally taciturn, rarely volunteered any remark, and when ill more quiet than usual; it was not considered very singular that she said little after the 22d, but in a day or two it was evident that she received fewer impressions than normal; she did not answer when addressed, but knew her friends, and could be easily aroused to partial consciousness. With the light furnished by the autopsy it seems probable now that there was word dumbness, and that the indifference was due to the loss of power to understand what was said. As this was not suspected at the time she was not examined with a view to discover such a condition.

When the convulsions began on the 28th the lesion was more clearly revealed. I thought then that there was probably meningeal hæmorrhage, and as the left side was paralyzed I located it on the right, yet the convulsions at first seemed most marked on the right. The left side of the face was convulsed, the right hand was tremblingly raised to the head. There might now be a reasonable doubt whether the motion of the right hand at this time was truly convulsive, whether it was not a voluntary or at least a reflex action, an attempt to carry the unparalyzed right hand to the convulsed side of the face. The next day the spasms affected the left arm, and the right side was scarcely moved during the convulsions.

The conjugate deviation of the eyes during the convulsions towards the convulsed and paralyzed side, in the interval between the convulsions away from the paralyzed side, caused me to definitely localize the lesion above the crura cerebri, that is, I thought the hæmorrhage was over the surface of the right hemisphere. Of course I did not attempt to diagnosticate the extent of the hæmorrhage; it was certain that the motor centres were irritated. It is interesting that the centres for the face and arms were covered by the clot, but the centres for the lower extremity were almost entirely free, and the spasmodic action was very slight in the leg.

The remarkable condition of the arteries and veins, filled with coagula, and the small ecchymoses in the brain and other organs, is explained by the interference with respiration. Several times she seemed to be dead, but by artificial respiration life was prolonged a few hours. The disturbance of respiration may have been due to the increase of intercranial pressure.

The above peculiarities made this case one of the most perplexing and interesting; perplexing until the spasms showed where the lesion was. Not that there was any doubt as to the presence of some kind of cerebral lesion after the attack of pain in the head, but its nature and location were in doubt.

CASE II. SPASM ON LEFT, COMMENCING IN EYES, EXTENDING TO FACE AND LIMBS. LOCALIZED MENINGITIS AND CORTICAL ENCEPHALITIS.

The second case presents symptoms very similar to those noted towards the close of life in the preceding. There is no history of the patient's condition previous to her entrance to the City Hospital, except that she had been quarreling with another woman, and was arrested for assault. In the morning she was found to be unconscious and in spasms, and was taken to the hospital. When seen about 9.30 A. M. she was unconscious, head drawn back, the back and legs were not in the position of opisthotonos. About once in a minute or minute and half occurred a convulsive seizure lasting from half a minute to a minute. The spasm com-

menced with conjugate deviation of the eyes towards the left and deviation of the head towards that side, then the left side of the face was affected, the eyelid winking rapidly, and the muscles of the lower part of the face twitching spasmodically; in a few seconds the left arm was drawn up in tonic contraction, then almost immediately it was in clonic convulsions, and finally the left leg was slightly affected. After running through the whole side the spasm soon subsided and the patient became quiet; then both eyes were turned to the right, and this conjugate deviation to the right persisted during the interval between the attacks. In the interval also the left hand was limp and fell heavily when raised; the right arm fell slowly, and once there was a spontaneous motion of the right hand.

The pupils were of moderate size, reacted slightly to light, the cutaneous reflexes were absent, the patella reflex was normal, no ankle clonus. There were such loud bronchial râles, groaning, and other noises made by the patient that the chest sounds were obscured. There was a slight œdema of the feet; the urine had a specific gravity of 1020, contained a trace of albumen, many hyaline, a few granular, casts.

By noon the convulsions had become less frequent, and by eight P. M. had ceased.

The next day the left arm was paralyzed, the eyes were turned to the left, head was still retracted, turned a little to the left; this contraction of the head was spasmodic, resisting efforts to correct the position.

She died about fifty hours after entrance.

Autopsy. Brain. On right, over posterior part of third and lower and posterior parts of second frontal convolutions, almost entirely in second and just lapping on third frontal convolution, not implicating ascending frontal, but coming up to it, was a very firm adhesion of pia and dura mater.

Moderate amount of serum in arachnoid, also moderate injection of vessels. On the right, over lower third of ascending frontal and ascending parietal, middle of first temporal and posterior part of second temporal convolutions pia had a distinctly yellow tinge. On left the whole of the third frontal convolution, and from the supraorbital, extending as far back as ascending frontal, showed a yellowish discoloration as on right. On the left, after removing membranes, the cortex over third frontal convolution in middle, fully one and one half inches antero-posteriorly, still discolored; discoloration not extending through whole of gray cortical substance. On right, on removal of pia, the spot which was adherent to dura was also adherent to the brain substance, and membranes could not be removed without damage to brain substance. The whole of the posterior part of the third and lowermost part of second frontal convolutions were yellow and flaccid as if covering a cyst, extending one and three eighths inches antero-posteriorly, and one and one quarter inches transversely. Ascending frontal and ascending parietal slightly discolored, ascending parietal rather more deeply, and at one spot cortex deeply changed. First temporal also slightly discolored, and posterior part of second temporal corresponded with discoloration seen through pia. (All this evidently an old condition.) Figs. 2 and 3.

Ventricles contained normal amount of fluid. Venæ Galeni much injected. Intra-ventricular portion of both optic thalami and anterior corpora quadrigemina had a decided yellow color. To a less extent posterior corpora quadrigemina had a yellow tint. On left side yellow discoloration in pulvinar extended half an inch deep, except at anterior portion, where it extended more deeply. On right side yellow discoloration penetrated pulvinar one eighth of an inch. Discoloration of corpora quadrigemina entirely superficial. Olfactory lobes both yellow.

No fracture of skull. Few ecchymoses of scalp.

Lungs. Old pleuritic adhesions. Posterior third of left lung acute pneumonia in second stage. Right lung acute pneumonia not so far advanced, also one inch above interlobular fissure and near posterior border of

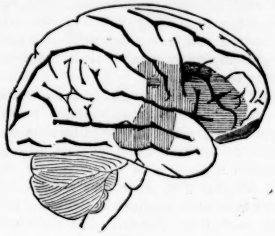

Fig. 2.

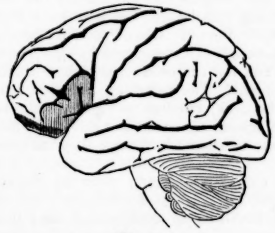

Fig. 3.

Figs. 2 and 3. Darkest horizontal shading shows the seat of firmest adhesion; lighter horizontal shading, seat of destruction of cortical substance; perpendicular shading, the portion having a yellowish tinge.

lung a recent infarction three quarters of an inch long, extending into lung in irregular conical shape.

Other organs not remarkable.

In this case by not taking into account my ignorance of the patient's previous history, and by considering that she had been in health up to the time of the first attack, I was led into error and diagnosticated an injury implicating or near the lower portions of the ascending central convolutions, or a meningeal hæmorrhage over this region. No injury to the skull could be discovered, therefore I thought it most likely there was hæmorrhage. The autopsy showed that the seat of the lesion was correctly defined, though it extended more anteriorly than was thought likely, but the nature of the lesion was different, being a chronic meningitis of long standing. The condition of the lungs was not recognized before death. The tracheal râles were so loud as to obscure the respiratory sounds, and also the convulsions attracted the greater share of attention.

Case III. Unilateral Spasm. Cortical Encephalitis.

M. F. was in the City Hospital several times. Probably in 1873 for rheumatism, though under another name; then in 1877 for intermittent fever. Again

under his later name he entered in March, 1880, having been found in his room delirious. He answered questions, but his talk was not quite intelligent. There was continuous trembling of the left arm and thigh; the pupils contracted equally; the tongue was protruded straight; there was no facial paralysis; there was a strong systolic souffle in the second intercostal space on the left and right. He had several rheumatic attacks, and was discharged relieved June 7th.

July 29th he was brought in again unconscious, said to have had several fits; he had several after entrance; the teeth were clinched, pupils contracted equally and insensible, left arm and leg twitched. In the evening he was excited and wild; the next day he was confused; right pupil was smaller than the left. He remained only two days.

October 11th he was brought to the hospital in a fit, and had many more after entrance. Twenty grains chloral and forty grains bromide potassium were given, after which the fits ceased and he slept all night.

No mention is made of a recurrence of the convulsion until October 23d, when the muscles of the left side of the face were noticed to twitch. The tongue protruded strongly to the left; the right side of the face moved a little more than the left. During the visit on the 24th he had an attack; the mouth was drawn strongly to the left, the jaws were slightly convulsed, while the left side of face, forehead, and ear twitched, the left eye was closed by spasm of the orbicularis. The right forehead and right orbicularis were also convulsed. The twitching extended to the muscles of the neck, but was not perceptible below the neck. A smart slap on the left side of the face caused the spasms to diminish, though they continued afterwards.

These convulsive seizures recurred frequently. I saw several, and it is noted a few times that there was conjugate deviation of the eyes and head to the left; the left arm and leg were sometimes contracted and tremulous. One day the twitching of face and arm was almost constant; once, later, the left side of the face was relaxed; the left eye was not closed. When seen asleep the face was quiet, on awaking the twitching returned.

The urine throughout was found to contain albumen, hyaline, and granular casts.

During the last part of his life one knee-joint became much swollen and contained fluid. Bedsores had formed, and he finally died exhausted.

Autopsy. Brain. (Figs. 4 and 5.) Right hemisphere. Membranes adherent over the cortex on both sides of perpendicular fissure, extending downward as far as inter-parietal fissure or a little below that, forward not quite to the ascending parietal convolution. Also a very slight amount of adhesions at base of fissure of Sylvius. The first temporal convolution was quite atrophied, about one half as thick as normal, and had a yellowish color. This color also extended backwards to the interparietal fissure and a little above the fissure of Sylvius. Around lower end of central fissure two or three small spots where membranes were adherent and cortex was removed with the pia mater. Over vertex membrane œdematous, considerable serum in subarachnoid tissue. Arachnoid thickened and opaque. At the base arteries all normal.

On left hemisphere color normal. No adhesion or atrophy except about an inch from median fissure on ascending parietal fissure, a spot one quarter of an inch long, one third of an inch wide, oval in shape where the membrane pulled off a thin layer of cortex. About half way between fissure of Rolando and anterior extremity of brain, implicating the second frontal convolution, and to a very slight extent the first, there was a cyst about three quarters of an inch in diameter.

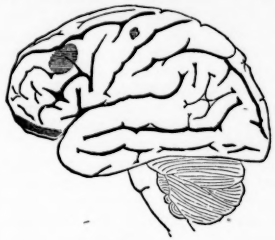

FIG. 4.

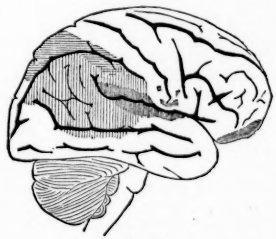

FIG. 5.

FIGS. 4 AND 5. Horizontal shading shows in Fig. 4 the location of the cyst; in Fig. 5 the points where the membranes were more or less adherent; perpendicular shading shows the parts which had a yellowish tint; the deepest shading where was the deepest tint.

On opening the ventricles the right optic thalamus bulged up more than the left, and had a yellowish hue.

The paracentral lobe on right side had somewhat of a granular appearance. Over the portion which was discolored yellow a very decidedly marked atrophy of cortical gray substance was noted, which was reduced in thickness about one fourth. The discoloration extended into fissure of Sylvius and implicated the island of Reil.

Lungs. Slightly œdematous and adherent in posterior and lower portions. Old cicatrices in apices. Bronchi contained considerable fluid of a serous character.

Heart. Not abnormal.

Spleen. Atrophied and anæmic.

Liver. Rather small, and on microscopical examination the acini rather granular and borders indistinct.

Kidneys. Rather small. Surface irregular and capsule adherent. Many Malpighian bodies were sclerosed; the convoluted tubules were granular.

Knee-joint. Much pus and fluid (synovial) and some crystals resembling fatty acicular crystals.

The cortex where least diseased showed simply an increase of spider cells in the outermost layer. As the amount of disease increased this layer of spider cells was somewhat thicker, but soon there was only to be noticed an aggregation of very small cells with relatively large nuclei. The blood-vessels running

through this layer were more prominent than in a normal cortex. This layer was not very firm, and was easily torn, so that in preparation it was sometimes impossible to avoid tearing it, and thus the outermost layer of the cortex was separated from the deeper parts. Where the change was most advanced the whole depth of the cortex was affected; many vessels were dilated much beyond the normal diameter. Where the change was less advanced the deeper layers of the cortex contained nerve cells which seemed to be healthy.

In these cases we have an example of unilateral spasm due to lesion of the cortex of the brain. In two the motor centres, which corresponded to the groups of muscles affected with convulsions, were most diseased; these were according to the rule. Not that these centres were more diseased than other parts; had they been those muscles would have been paralyzed, but they were evidently sufficiently affected to be the seat of an irritation. In the last case the centres for the affected muscles were apparently very slightly affected. Other parts of the brain were much more extensively diseased. Of course in judging of the seat of disease in cases of spasm due to cortical lesion we cannot limit the disease to exactly the motor centres. When it passes beyond those centres we may have no special symptoms developed to show us how far it has extended.

Conjugate deviation of the eyes due to spasm was present in all these cases. It followed the normal course as it is seen when due to lesion of the hemispheres, towards the side on which the limbs were convulsed. The rarity of conjugate deviation of the eyes from spasm makes this feature of the cases of interest.

WHAT IS MEANT BY NERVOUS PROSTRATION?[1]

BY ROBERTS BARTHOLOW, M. D., LL. D.,

Professor of Materia Medica and General Therapeutics, in the Jefferson Medical College of Philadelphia.

THE popular conception of the condition now known as "nervous prostration" is a state of debility, in which nervous derangements predominate. A man actively engaged in business or in public life presently finds himself unequal to his daily tasks; he suffers odd sensations in his head; his digestion is disordered; he is weak; wakefulness, mental depression, and a thousand and one new sensations of strange character and fearful portent are superadded. The unfortunate subject of these ills now recoils from his work, gives himself up to the consideration of his symptoms, and relaxes his hold on the interests and occupations of his life. All the world declares that he has "nervous prostration," and this explanation satisfies. Physicians say "neurasthenia" or "hypochondria," according to their habits of mind or to their training. Sometimes this condition is called the "American disease." Indeed, there is a general notion, widely prevalent, that neurasthenia is a peculiarly American malady. The late Dr. Beard was the apostle of this dispensation, and he not only was noisy and persistent in his advocacy of that view, but claimed, indeed, to have first clearly defined neurasthenia, and to have classified under this designation the numerous symptoms pertaining thereto. If we cannot admit Dr. Beard's claim in its entirety, if we experience repulsion at his tremendous but unconscious egotism, we are still compelled to acknowledge that his work in this connection is the most important that has appeared. He was peculiarly fitted to differentiate this malady by reason of the quickness and acuteness of his intellect, his power of analysis in its subtlest aspects, and his far-reaching, his omnivorous faculty for related facts.

The term *neurasthenia*, advocated by Beard, is by no means of recent origin. The corresponding French word, used in the same sense as we now employ it, has been a stock word of French neurological medicine for fifty years. Under the terms spinal irritation, hysteria, hypochondriasis, the nervous state, etc., symptoms of the same character as those now included in the word neurasthenia have been described. Besides the general state, similar derangements of functions of particular organs have been separately considered, as palpitation of the heart, headache, flatulence, impotence, etc. In the word neurasthenia — popularly, nervous prostration — the whole morbid complexus is included. The question I have to consider is whether this is a real, a substantive disorder. Are the notions now generally entertained about it founded on a true conception of the condition?

I need not enlarge on the importance of a correct understanding of a morbid state, which is supposed to be due to the conditions of modern, especially of American, life. Without stopping now to question the soundness of the prevailing doctrine, I will place before you the clinical history of two cases, representatives of the two types of neurasthenia. These may be designated respectively as the *congestive* and the *anæmic* varieties. The latter are greatly more numerous, but the former are not uncommon, as Beard admits.

CASE I. THE CONGESTIVE TYPE.

Mr. ——, aged forty-four, president of one of the largest railroad corporations of the West. He is now a robust man, five feet ten inches in height, 196 pounds in weight, and has a very dark complexion, his type of constitution being the so-called bilio-nervo-sanguineous. Beginning his career at an early age in a subordinate position, he has, by the force of a superior intellect and of a physique that no labor could subdue, risen to the highest office, and now controls vast interests. Ambitious, enterprising, resolute, he has carried these faculties into all his work, and has shrunk from no tasks, however severe — from no responsibility, however onerous. As he has risen in position, social engagements have also added to his burdens. His mode of life has changed to some extent. His habits have become more sedentary, although diversified by frequent railroad journeys; the pleasures of the table, including wine-drinking and late suppers, have been more and more indulged in; excessive smoking has been added to these indulgences; and thus, whilst his physical powers have been slowly impaired by bad hygiene, the demands on his mental powers have increased. Extensive interests, uncertain, often precarious, business arrangements, and the incessant watchfulness required when vast combinations may be wrecked through failure at any point, demand the highest use of every faculty; and thus to work is added worry.

Three years ago Mr. —— observed that he was not feeling well, and that he could not work as before. He became dull, especially after meals, had a constant headache, dizziness and throbbing of the temples; he

[1] Read before the Philadelphia County Medical Society, December 19, 1883.

applied his mind with difficulty, and all of the head symptoms were increased by the efforts made; he had a good, rather a keen appetite; a heavily coated tongue, flatulence, constipation, and some colic pains. The bladder was rather irritable, especially at night; sexual inclination had declined with lessened power, and various ill-defined but annoying sensations were felt about the penis, scrotum, and perinæum. During the first year the symptoms increased; the attacks of vertigo were sometimes very severe, so that he had to support himself for a moment to save him from falling. On several occasions he became very much dazed, even lost consciousness momentarily, and once wandered some distance from the proper route he was taking. Anomalous sensations of creeping and crawling, coldness and tingling, and often a burning heat, were felt in the scalp; sudden detonation in the centre of the head apparently; buzzing and singing in the ears, and very constant headache, were also experienced. In the extremities, the tongue, and the genitals, there were felt peculiar tingling, numbness, coldness, creeping, and similar sensations. During the whole time of the existence of his symptoms Mr. —— suffered from depression of spirits, a deep melancholy in fact, and he lived in constant apprehension of failure of mind.

Physicians whom he consulted in the West located the malady in the brain, diagnosticated cerebral hyperæmia, the prelude to softening.

When Mr. —— came to see me, sixteen months ago, the symptoms just detailed continued, and were rather increased than diminished. The objective examination furnished the following details: —

His face is full, the eyelids puffy, and the lower lid swollen into a bag; the conjunctivæ are injected, the sclerotic muddy, and the pupil sluggish in movement. On ophthalmoscopic examination, the fundus is seen to be injected, small vessels prominent, veins swollen. There is no optical defect, except that due to his age. The membrana tympani is also rather deeply red, and vessels too small to be seen under ordinary circumstances are now in view. Hearing is unaffected. Motility, sensibility — the tactile, pain, and temperature senses — are unaffected; and the reflexes remain normal, although probably a little sluggish. The electrical reactions are normal.

His tongue is heavily coated, the breath foul. His appetite is good, but a sense of fullness at the epigastrium persists for several hours after meals; acidity and eructations of rather foul gas now and then occur. The stools have the normal appearance — consistence, color, and odor. The urine is copious, acid, specific gravity rather high (1025 to 1030), and there are traces of sugar, as is usual under such circumstances.

The action of the heart is good, the pulse regular, the tension of the vessel rather high. The respiratory movements and murmurs are normal. The area of hepatic dullness is rather enlarged, and the splenic dullness seems, also, to be increased.

Subjectively the following symptoms are experienced: Various strange sensations in the scalp; a persistent headache; blurred vision at times; vertiginous feelings occurring irregularly and of varying severity; despondency, vague apprehensions; fear of places, especially of crowded assemblages; difficulty of deciding questions very trivial or otherwise, in place of former promptness; impaired memory for persons, names, and things.

Notwithstanding this extended list of symptoms Mr. —— did not have an ill look, but, on the contrary, on superficial examination, appeared to be robust. To him and to his immediate family the situation seemed in a high degree alarming. The surrender of his position and his business interests was regarded as imminent. To the apprehension awakened by his head symptoms was added the diagnosis of cerebral congestion, and hence the profound melancholy into which he was plunged.

Commentary. My conclusion was that the disturbance in the functions of the brain and nervous system were secondary to derangement of the assimilative processes — of the primary and secondary assimilation — and that to the functional disorder thus caused are added the effects of introspection and the realization by the centres of conscious impressions to an unusual extent of ordinary peripheral excitations. My reasons for coming to this conclusion will appear hereafter. The remedies consisted in a careful regulation of the diet, in baths, exercise, in a reduction of the hours devoted to work, but not the cessation of work; in the use of a laxative quantity of sodium phosphate daily, and in the administration of the aqueous extract of ergot, with the chloride of gold and sodium, and a minute quantity of bichloride of mercury. If time and space would allow the details of the hygienic management — so important in these cases — could very profitably, I think, occupy our attention, but I must pass on to the next case.

CASE II. THE ANÆMIC TYPE.

Mr. ——, aged fifty-seven, lawyer by profession. His type of somatic constitution is the nervo-sanguine; weight, 145 pounds; height, five feet nine inches. He has immense mental energy, extraordinary quickness of perception, a capital logical and critical faculty, and fine oratorical power. These native abilities, conjoined with extensive cultivation, soon placed him amongst the foremost men at the bar of the city where he practiced, and have long maintained him in that position. For many years he has been a dyspeptic, and suffered much from eructations of gas, from acidity and flatulence. At times — months, even years intervening — he has experienced very severe seizures, accompanied by extreme mental depression, alternating with as extreme mental exaltation. During the past five years he has had two attacks of gout, neither severe nor protracted. During the whole course of his professional life he has sustained no reverses, encountered no other anxieties than those of a successful lawyer, and has been rather singularly free, indeed, from the worries of life. Receiving, last summer, the nomination as a candidate to an important office, this cultivated gentleman, scholar, and lawyer, this man of nice tastes and high tone, entered on a canvass marked by vituperation and slander to an unusual extent. About the same time some business interests became entangled and caused no little worry. During the campaign he visited some malarious districts, and spoke several times at night in the open air. A speaker of great readiness and power, he never suffered from any considerable fatigue after public speaking, and hence he was now surprised to find himself exceedingly tired after even a brief effort. He began to have drenching night sweats, lost his appetite, grew weak, and was compelled to return home. It was then ascertained that he had malarial fever, and he was treated accordingly. But at this time and subsequently symptoms not necessarily of malarial

origin appeared. He became frightfully dyspeptic, had enormous eructations of gas, and very considerable flatulence; his arms and legs had a numb feeling, attended with "pins and needles;" he walked with some difficulty, partly because of weakness; he was somnolent, and slept a good deal, and his spirits were extremely depressed, especially on awaking in the morning. During these periods of depression he was so overwhelmed with despondency that he was apprehensive he would lose his self-control entirely.

When he placed himself under my charge he had still a slight daily paroxysm of fever, the exacerbation occurring in the morning, but this disappeared in a few days under the action of some efficient doses of quinine. He was very weak, pallid, and emaciated, and slept a good deal of the time. He had no headache; his vision was rather dull, and ideas and speech slow. Every morning on awaking he was profoundly melancholic, and all the annoyances which the campaign had developed were gone over in his mind. He could talk of nothing else, think of nothing else than his ill feelings and the disagreeable political and personal slanders of which he had been made the victim. He complained much of the numbness of his hands, of weakness in the limbs, and he talked incessantly of his depressed feelings. The bladder became irritable, and he was compelled to rise every two or three hours during the night, the urine being acid, and depositing heavily of uric acid. Presently the somnolence was displaced by insomnia, and he slept less and less, and rose in the morning haggard, exhausted, and horribly nervous and depressed. Ordinary hypnotics proved unequal to the effort to force sleep, and increasing doses of chloral became necessary. His mental activity, heretofore so remarkable, declined, and the effort to force his mind to the performance of any work, such as letter-writing, caused a sensation of fatigue. He also became undecided, even in small matters, ceased to have any inclination to go out and mingle with the public, and grew more and more averse to political movements. He reached a point finally when to meet strangers caused him great distress, excited the circulation, and induced a cold sweat.

As it became indispensable that he should resume the canvass he made a strong effort, and notwithstanding the fatigue, mental and moral depression, and exposure of public speaking, hand-shaking, and other matters of political expediency, he actually improved somewhat. The insomnia, irritable bladder, and hypochondriasis, however, continued, but to a less degree. In a few weeks, by means chiefly hygienical, I succeeded in stopping the chloral; natural sleep was resumed, although it remained somewhat fitful. Suitable dietetic regulations, baths, exercise, and medicines, *pro re nata*, removed, or at least greatly modified, the principal symptoms. Two weeks at Atlantic City accomplished no little good, and when he returned to Philadelphia last week he appeared to be nearly his old self.

Commentary. In this case we have exhibited that complexus of symptoms entitled neurasthenia or nervous prostration in its anæmic form, produced by several factors, moral and somatic. The moral were very influential, but unless the conditions producing bodily depression had occurred, the former causes could hardly have effected such results. Long-standing dyspepsia had prepared the way, malarial intoxication and fatigue contributed an important series of changes, and upon this weakened bodily state were precipitated crushing moral influences.

These cases whose histories I have just read are typical; each is the representative of a group. The causes are complex. The effects are not limited to one organ or set of organs, but involve the system in general. To name this malady from the disturbance in one system seems to me an error unless the definition is sufficiently elastic to include all the functions affected. Neurasthenia names one only of the parts involved. To entitle this the "American disease" is a strange misnomer. It might with more propriety be called the "French disease," for a condition known as "the nervous state," as "nervism," as "neurasthenia," and similar terms, has been recognized and frequently described by French writers from an early period in this century. In France have existed the causes in the most influential form. The frequent political convulsions, the exacting social life of the great cities, and the harassing struggle for existence inseparable from the state of the great mass of the population induce — if any mere external conditions can — that which is called nervous exhaustion. There are two factors supposed to be especially influential in this country, work and our exciting political and social life. I believe that the effect of these is greatly overrated.

The brain, of all the organs of the body, illustrates in the most perfect manner that which has been happily styled "the principle of least action." That is, to execute given tasks it expends the least possible force, or, to express the same idea in another form, its work is done with ease with the minimum of effort. Given a certain amount of repose — sleep — and supplied with proper nutriment — healthy blood — the brain will do its allotted work continuously during its working — the waking — hours. So far from being injured by severe labor carried on under normal conditions, the brain is improved by it. Mental activity, like muscular exercise, keeps the brain in a healthy state. When, therefore, a man says he is suffering from the effects of mental overwork I want to know what his vices are. Worry may be one of these. Worry is exhausting. The worries of life do infinitely more harm than the work of life, how onerous soever it may be. The cases I have just read illustrate this.

I deny that life is more exciting on this side of the Atlantic. The one prize of life is money, and to get possession of it is the supreme purpose, to the attainment of which every energy is put forth. Is it less so elsewhere? Who are the peoples that despise money, and make no effort to obtain it? Here life is less exciting because our political condition is stable, and but comparatively little exertion is required to secure a comfortable subsistence. I am speaking now of the mass of the population, and not of the few consumed by ambition for political and social distinction, or led by a pitiless greed. It is the very ease and luxury of our American life that cause mischief. It is the indulgence in eating and drinking, the abuse of alcohol and tobacco, sexual excesses, sedentary habits, and too luxurious lives generally that induce the state of the system called nervous exhaustion. If I had time each of these should be considered in relation to this subject. In the first case I narrated the pleasures of the table and disordered assimilative functions caused the trouble. In the second case, dyspepsia, malarial toxæmia, and unusual fatigue were the pathogenic factors. In both the effects of these causes were increased by moral in-

fluences; in one, the anxieties involved in vast business enterprises; in the other, the excitement of a hot political contest. These moral causes would have had no injurious effect had not the somatic conditions been unfavorable.

I come now to the most difficult part of my subject. I have to answer this important question: Why are the somatic derangements caused by the conditions referred to in some cases accompanied by the mental and nervous symptoms which belong to neurasthenia? Why do some subjects with indigestion and assimilative disorders, or with the results of dyspepsia and malaria, suffer from the derangements of the mental and nervous functions and not others? I might here take refuge behind an accepted generalization, and say that the presence or absence of the neurotic type of constitution explained the difference in the result. There is aptness in this explanation, but it is not entirely adequate. There is a mental condition of great importance, and unless we comprehend this we fail to realize all the possibilities of the nervous side of these cases. I, however, barely hint at the main points under these circumstances. Besides, I wish to avoid a too metaphysical discussion of the subject.

In the conduct of life every man who has a position to make or to maintain exerts a certain moral force to hold himself up to his work. Some men are so happily constituted that they are quite unconscious of the effort and stand in the front, serenely confident. Others are all the time laboring; they feel it and know it; and like the soldiers of Thomas's corps at the battle of Chickamauga, sorely pressed, now and then look back to see whether their grim and resolute commander is still behind them with his invincible courage. Men conscious of the effort making to keep up need but little excuse to surrender themselves to their sensations. At the present time nervous prostration is much feared; its symptomatology is a common subject of discussion; and hence, if a man who is familiar with its character is arrested in his career by some of the ailments supposed to belong to it, his imagination readily supplies the rest. When a man begins the study of his bodily sensations, having a certain model in his mind, he has little difficulty in filling out the details. All the world knows that when the attention is strongly fixed on an organ of the body functional disturbances of it ensue, and finally structural changes may be induced. No part of the body is without sensation, even in health. To perceive these sensations the attention needs to be withdrawn from external things and concentrated on the part. Thus it is when the subject of neurasthenia pursues his introspection; he becomes conscious of numerous sensations, which, because now felt for the first time, are new. Under these circumstances, also, the seat of conscious impressions becomes more acutely perceptive. Suggestion adds its quota of symptoms.

To the indefinite and multiplying nervous symptoms developing thus subjectively must be added the reflex. Headache, vertigo, tinnitus aurium, amaurosis, diplopia, hallucinations and illusions, defects of speech, paralysis, are reflex symptoms on the part of the brain; palpitation, intermittent pulse, angina pectoris, laryngismus stridulus, asthma, are amongst the reflexes of the respiratory organs and heart; neuralgia, anæsthesia, and other disorders of the sensory nerves, and local paralyses, affections of the motor nerves, included amongst the nerve reflexes, may all be dependent on reflex excitations proceeding from the stomach. Indeed, there is no symptom in Beard's catalogue of those belonging to neurasthenia that may not be due to merely reflex influences having their initial seat in the digestive apparatus. It follows that the term neurasthenia, or its common equivalent, nervous prostration, is either inadequate or it expresses too much, — inadequate if the complex of symptoms includes the functional disturbances of all the organs affected, expresses too much if the malady is a merely nervous one.

In reply to the question: "What is meant by nervous prostration?" I respond, "A disease usually functional, situated in one or more organs, during the course of which reflex disturbances of the brain occur, and numerous subjective sensations in all parts of the body are realized by the consciousness."

I deny that neurasthenia is a primary nervous affection, or that it is a substantive disease. I hold that it is symptomatic and secondary.

This conception fixed in the mind, the treatment of neurasthenia is successful or unsuccessful according to the measure of our skill in localizing the initial disturbance, and in addressing our remedies to that as well as to the general state.

THROMBOSIS AND THE CONDITIONS WHICH FAVOR ITS DEVELOPMENT.[1]

BY C. H. BROCKWAY, M. D., LYNN, MASS.

SAYS a recent writer, "There is no more intricate problem awaiting solution at the hands of the clinical and pathological investigator than that of the clotting of the blood in the vessels during life." And I think I do not overstate the case by saying that no more appalling accident is brought to our notice from time to time than the sudden supervention of thrombosis or embolism, alarming and distressing the patient, — if, indeed, he escape immediate dissolution, — terrifying his friends, and causing the gravest anxiety to the physician. This event, moreover, is seldom looked for, but comes with startling suddenness in the course of diseases and morbid conditions which up to that moment had apparently been progressing favorably.

Let us look for a moment at the conditions which favor thrombosis. (1.) A stagnant or arrested circulation, as in some cases of pulmonary thrombosis, in which the clots in the arteries are probably the result of obstruction in the circulation through the lung capillaries. (2.) A mechanical obstruction around which coagula form. (3.) And most important of all (as Playfair says in writing on this subject) cases in which the coagulation is the result of some morbid state of the blood itself.

There is, probably, no condition in which the predisposing causes of thrombosis exist in so marked a degree as in the puerperal state, and many of them are clearly exhibited even during the period of gestation. In pregnancy the blood is more watery, is deficient in red globules, and contains a larger proportion of fibrine, which must be looked upon as a waste product. So long as the excrementitious elements generated in the mother's system and that of the fœtus are freely eliminated all is well, and this natural expelling of waste products goes on without disturbance while the lungs,

[1] Read before the Essex South District Medical Society at Salem, December 18, 1883.

heart, and glandular system generally are in good working order; but if for any reason the elimination of effete materials is impeded there is at once a gathering of noxious matters in the blood which promptly poisons that life-giving fluid. And yet notwithstanding the excess of fibrine and proneness of the blood to clot during pregnancy, thrombosis is rare in this condition, the eliminative processes being ordinarily active enough to carry away the waste products; both nervous and vascular tension are high, and the glandular system works with rapidity. The marked exception as regards the kidneys, however, demands a passing remark. There are cases of sufficient frequency to come under the occasional notice of each one of us in which the kidneys fail in their proper office and permit the excrementitious elements of the urine to be retained in the blood. In such an event that fluid is loaded with a morbid and poisonous material composed not only of urea but probably of other effete materials which would be eliminated in a freer state of the abdominal circulation. In death from this form of poisoning thrombosis does not occur (so far as I can learn). If the theory of Richardson be tenable this fact may be accounted for by the presence of large quantities of carbonate of ammonia in the blood of those suffering from uræmic intoxication, thus keeping the fibrine in a state of solution.

The great majority of cases of thrombosis in lying-in women occur a variable number of days after delivery. What are the new conditions left by labor which predispose the patient more than ever to the accident of blood-clotting in the vessels. The frequency of the heart's action has been much lowered and vascular tension diminished. The drain of blood following the birth has been considerable, perhaps excessive; this causes an increased activity of absorption of good and bad material alike. During pregnancy the waste products are gotten rid of without much difficulty, the excretory organs working hard under the stimulus of a heightened vascular and nervous tension. After labor, with that tension lowered, the eliminative system is called upon to do a much greater amount of work. In fact it is in danger of being overstrained. As soon as uterine involution is well under way a great quantity of noxious material is poured into the blood. In most cases, to be sure, this is quietly expelled by the natural processes, and no untoward event occurs, but no one can for a moment doubt that the woman is in a precarious condition. This irruption of effete matter is apt to furnish that very ferment (for want of a better term) which recent writers declare to be necessary to precipitate in various localities the fibrine which was already in excess in the blood. The thrombosis thus produced is often a *conservative* measure, inasmuch as coagulation is apt to first take place in the uterine veins and pelvic vessels generally, thus protecting the blood as a whole from immediate infection. These venous plugs or thrombi after a time undergo a process of disintegration with a view to their ultimate removal. During this period one of the clots may become loosened from the wall of the vessel or a portion may break off from the main body of the coagulum and, entering the systemic veins, be carried along by the venous current until it reaches a vessel too small to allow of its onward progress, where it remains, plugging that vessel and, of course, producing the same symptoms as if a thrombus had originally formed at that point. This migratory plug is an embolus, showing that embolism is but an accident of thrombosis, and cannot occur but as a sequel to that event. When a clot is loosened from one of the pelvic veins and passes upward it usually ends by plugging the pulmonary artery or one of its branches, and thus causing those terrible results of pulmonary obstruction which so often end the life of the patient. It was formerly asserted by the most eminent German pathologists that this obstruction was *always* due to an embolus, and that primary thrombosis in the pulmonary arteries was an impossibility. This view was combated by Playfair, who produced many clinical facts to support his belief that coagulation of fibrine took place in the right side of the heart and pulmonary arteries. He reports twenty-five cases of sudden death after delivery in which accurate post-mortem examination had been made, and the results are important and instructive. In seven of them there was distinct evidence of embolism, and not one of those patients died before the nineteenth day. In fifteen of them no evidence of embolism was found to account for the plugging of the pulmonary vessels; they all died within two weeks with one exception, and some in two or three days. The fact of death occurring so soon is in itself against the theory of embolism, as time is required to induce those degenerative changes which lead to the separation of a clot in the peripheral vessels.

Thus far I have briefly sketched the chief conditions which favor thrombosis, and have drawn illustrations from puerperal cases because the literature of the subject is comparatively rich as applied to lying-in women, and it is through these reported cases, and the commentaries that have been made upon them, that the majority of the profession has been instructed in the effects of blood-clotting in the vessels during life. But this affection, as you well know, is not peculiar to pregnancy and the puerperal state.

It may and does occur as a complication of common diseases, and this paper is especially written to draw your attention to this fact, and to illustrate it by two cases of scarlatina occurring in my own practice, in which there was strong evidence of thrombosis of the pulmonary artery. The first patient was a boy of ten years, enjoying previous good health. He was seized with scarlatina. The eruption came out freely, the fever was high (105° F. the second evening), but not unusually so, and there was nothing about the case to cause any anxiety until the sixth day. At this time the boy showed symptoms of marked exhaustion, the eruption had considerably faded, and the cervical glands, which had been moderately swollen for two or three days, suddenly grew large and painful, the pharynx was congested, and there was some pain on swallowing, but the symptoms referable to the throat were not significant. He breathed naturally, and there was nothing to draw one's attention to the chest. His appetite had failed, and he looked decidedly ill without any assignable cause other than the general blood-poisoning common to the disease. This on the sixth day. On the afternoon of the seventh I was hastily summoned, and found him suffering with horrible dyspnœa and gasping for breath. The attack had come on suddenly, so the father said. The boy's face was rather pale. When I first arrived, only a few minutes after the attack came on, the heart was beating tumultuously; the respiratory sounds were natural. Strong mustard poultices were applied to the front of the chest, and brandy with the aromatic spirits of ammonia was

freely given. In half an hour the heart beat grew feebler and fluttered, the respirations became very short, and he was soon dead.

No post-mortem examination was allowed, but I think the symptoms were too significant to admit of any doubt regarding the occurrence of pulmonary obstruction, and that from a coagulum in the right heart, and extending into the pulmonary artery.

The next case was also a boy, a trifle younger, perhaps seven years of age. In him the eruption was well developed, and the fever active for a few days, when he showed marked signs of exhaustion. With the other case fresh in mind (both occurring the same year), although there was nothing in this child's condition to warrant an expectation of heart clot, I watched him carefully, and took pains to have him well nourished and the secretions kept in an active condition, at least the skin and bowels, the latter acting rather freely of themselves. The urinary secretion was fairly good; there was a trace of albumen in the urine, if I remember aright, but no œdema or uræmic symptoms. I gave him the carbonate of ammonia in two grain doses every hour. This was not well retained, as he vomited frequently both medicine and food. This irritability of stomach I had noticed in the boy before when treating him for various disorders. The parents considered that he always had "a weak stomach," as they termed it, and this symptom did not alarm me. He was bright, and complained of no head symptoms. This was his condition after he had been ill a week and a half, when his father came in haste for me one evening. I found the boy greatly distressed for breath, a symptom which had come upon him suddenly. His dyspnœa was nearly as great as in the fatal case above narrated. His heart beat rapidly and was feeble. His respirations were of a gasping character. He was given brandy by the mouth and rectum, and mustard was applied to the chest. This relieved the violence of his dyspnœa somewhat, but yet he was evidently in a critical condition. The attempt at stimulation by the mouth was soon abandoned as he instantly rejected it. The vomiting had no apparent effect upon his breathing. He continued in this way throughout the night, being worse at times, but relieved by the stimulant, and especially by having him breathe an atmosphere surcharged with the vapor of water, as is customary in cases of croup. The next day he was more comfortable, though still much distressed. He was kept quiet, sinapisms applied to the chest, and brandy given at intervals when his symptoms demanded it. He gradually recovered. It may be doubted whether this was a case of pulmonary obstruction, but the symptoms were well marked, and to me unaccountable on any other hypothesis.

Playfair records a number of cases of recovery with symptoms the same as above recorded occurring in women after labor. As he says, "if the obstruction be only partial and sufficient blood pass to keep the patient alive," recovery is surely not impossible.

Cases of sudden death from thrombosis occur now and then in diphtheria. Flint says that he lost one patient in acute rheumatism from the sudden occurrence of a coagulum in the right ventricle, passing into and obstructing the pulmonary artery. Tanner believes that the sudden death of many patients with croup is due oftener to thrombi than to asphyxia.

One word as to treatment. In the way of preventive medicine I know of nothing unless we give as a routine practice the carbonate of ammonia in large doses in all cases whenever we have reason to think the occurrence of heart clot possible. But this hardly seems practicable, and its efficacy is doubtful. The eliminative organs should be kept in active condition by every means in our power, and I have thought that the sulphite of soda might be freely used with benefit in all septic conditions of the system.

Hospital Practice and Clinical Memoranda.

TWO CASES OF UTERINE POLYPUS.[1]

BY FRANCIS MINOT, M. D.

THE first patient was a married woman, forty-nine years old, who had never been pregnant. General health good till about three years ago, when the menstruation became frequent and profuse. For the past three months the hæmorrhage had been continuous. She entered the Massachusetts General Hospital in a very anæmic and debilitated condition. The uterus could be felt above the pubes, and was not apparently enlarged. On vaginal examination the cervix was found to be very large, spherical in shape, with an opening in the presenting part into which the finger could penetrate with some difficulty. A smooth, hard mass was felt within it, not adherent to the walls of the cervix. On account of want of space the pedicle of the tumor could not be felt. A loop of twisted wires was passed over the tumor and tightened by an écraseur until the pedicle was cut through. The tumor was then removed without much difficulty, the os being incised in two directions to permit its exit. The vagina and cervix were carefully sponged out with a solution of carbolic acid, and the vulva was covered with salicylated cotton. Scarcely a drop of blood was lost. The perinæum was frequently bathed with carbolic acid solution. The operation was done March 16th. The next day there were no symptoms, but on the 18th the temperature rose to 100° F., and carbolized vaginal douches were ordered. On the 19th there was a chill; on the 20th, vomiting. The temperature continued to rise, the abdomen became tympanitic and tender, and she died March 22d at midnight. The tumor was an ordinary fibroid of the size and shape of a lemon. In addition to the carbolic douches eight grains of quinine were given every four hours, besides morphia, etc. It was found, after the patient's death, that there was a case of erysipelas in an adjoining room, and, notwithstanding the precautions taken, there can be no doubt that the fatal result was owing to septicæmia originating by contagion.

The second case was that of a married woman, who entered the hospital at about the same time as the above, and whose history was almost identical with hers. The tumor was wholly extruded from the uterus, and occupied the vagina. It was somewhat smaller than the first, and was nearly spherical. It was drawn down with hooks, and separated from the stalk before the latter could be severed with scissors. The patient was carefully isolated, and every precaution was taken to prevent infection. There was no untoward symptom, and she left the hospital in a few days, well.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES H. WILLIAMS, M. D., SECRETARY.

At a meeting of the Boston Society for Medical Observation, held November 5th, Dr. C. M. Green reported the following

CASE OF MAMMARY CANCER. OPERATION. SUBSEQUENT CATARRHAL PNEUMONIA, WITH CANCER OF THE LUNGS. AUTOPSY.

In January, 1882, I was consulted by Mrs. T. on account of a small tumor of the left breast. The patient, a widow, forty-five years of age, the mother of one child, had been for several years in poor general health. Although in fairly comfortable circumstances she had worked very hard; her appetite was fickle; her digestion poor; and she rarely partook of animal food. She had passed the climacteric a year and a half before without incident. One year before I saw her she noticed a slight, non-offensive discharge from the left nipple, which was somewhat excoriated and sore. At times the discharge would cease and the soreness disappear. Four months before she consulted me the nipple was noticeably retracted, and three months later the discharge began to be offensive.

On examination the gland was found to be hard, the size of a small orange, and the nipple retracted; the integument was firmly adherent to the gland, and was excoriated about the nipple; there was a sero-purulent discharge sufficient to stain the linen. No enlargement of the axillary glands could be detected. I considered the growth to be cancerous, and advised its immediate removal.

A few days later I excised the entire gland by the usual operation, removing all the subcutaneous tissue, and as much of the integument as I thought necessary. There was very little hæmorrhage; four or five bleeding points only were tied with carbolized catgut. A drainage tube was inserted; the skin united with catgut sutures covered with antiseptic gauze, and supported with adhesive straps and a binder. There was but slight discharge from the tube, and on the fifth day union by first intention had apparently taken place except over a small extent. But two days later most of the sutures were found to have dissolved, and the wound gaped. The drainage tube was, therefore, removed, and the wound dressed with carbolized oil and left to granulate. Two weeks after the operation the patient was eating more than she had for years and was in every way comfortable. The wound was filled with healthy granulations.

Dr. W. F. Whitney very kindly examined the tumor and pronounced it to be scirrhous cancer. He found, too, to my regret, that cancerous digitations had been cut across by my incision on the sternal side; and I, therefore, watched the case with expectation of a recurrence of the growth in the cicatrix. I determined, too, that thereafter I would follow the advice of Professor Gross and remove the integument more freely, even at the expense of a large suppurating wound.

The patient continued in good general health until the following December, when she took a cold from sleeping in a room, the ceiling and walls of which had been wetted through a leaky roof. This cold proved to be the beginning of the end. Although improving in some respects, in the following March the patient had lost flesh and strength and suffered much from cough and dyspnœa. There were fugitive sibilant râles over the entire left lung; sibilant and abundant fine moist râles over the right scapula and at the base of the right lung, with dullness on percussion. The expectoration was scanty and of a white, frothy character. There was some pain under the right scapula. It was clearly, to my mind, a case of catarrhal pneumonia. In April fine, moist râles were heard also over the base of the left lung, and the respiratory murmur was harsh over both apices. The pulse was rapid and weak; the respirations increased in frequency and shallow; the cough and dyspnœa considerable. There was pain and a sense of suffocation referred to the epigastrium.

The treatment adopted alleviated the symptoms, but the disease pursued the usual course. With the knowledge of the preëxisting cancer of the breast I was, of course, alert to discover symptoms of a secondary growth elsewhere. There was as yet no return of the growth in the cicatrix. Although later on there was great pain through the base of the left lung, requiring morphia, it was apparently ascribable to pleurisy, and the physical signs were at no time indicative of pulmonary cancer. Nor was I able to discover any physical evidence of cancer of the stomach, although a sense of pain and constriction in the epigastrium and occasional vomiting pointed to the possibility thereof. Early in June the temperature was for the first time observed to be elevated. From this time decline was progressive, and death occurred one month later. The day before death the patient vomited blood once or twice. At the time the explanation was not clear to me, but the post-mortem examination revealed the source of the hæmorrhage.

The autopsy was made by Dr. Gannett twenty-six hours after death. His report is as follows: —

Body medium-sized, fairly developed, much emaciated. Rigor mortis present. The left breast absent, its seat occupied by a healed cicatrix, by estimate fifteen centimetres long. Diaphragm right and left at the upper border of the third rib. Pericardium contained about forty centimetres of clear fluid. Pericardial surfaces not remarkable. Heart diminished in size; left ventricle contracted and empty; right ventricle and auricle moderately distended with dark-red coagula. Aortic valves sufficient; mitral admitted tips of three, tricuspid tips of three, fingers. Valves and cavities not remarkable. Muscular substance of a dark-brown color. Coronary vessels not unusual.

The left pleural surfaces, adherent laterally and over apex by tolerably firm adhesions; on the right side pleural surfaces adherent throughout by firm adhesions. The left pleural cavity contained no fluid. Both lungs only partially retracted; showed numerous irregular depressions, with here and there portions of lung substance projecting considerably above the surrounding parts; such portions were pale, and showed beneath the pleura numerous alveoli as large as pins' heads. On pressure over the left lung numerous small nodules could be felt within. On section of the left lung, at the apex, were several cavities, varying in size from a pea to a filbert, with nearly smooth walls and thick curdy contents. In the lower lobe were numerous gray, firmer nodules about the size of a large pea; from many of these small drops of a puriform fluid could be squeezed. There were also a few grayish,

slaty nodules, denser than the last, and with irregular borders. The right lung had similar appearances, except that there were no cavities in the apex, and the nodules were far more numerous in the lower lobe, making it dense and firm. In several places in this lung the walls of the larger bronchi were much thickened; many of the lumina contained cheesy or puriform material.

Examination of various parts of the lungs after hardening gave the following appearances: The peribronchial connective tissue very much thickened in many places, and in it were numerous long and rather narrow spaces or alveoli filled with large epithelial cells atypically arranged. The lung substance in the immediate neighborhood had a similar appearance. Many of the smaller nodules described above showed a mesh-work made up of the usual lung structure, but the spaces were filled with nests of large, well-defined epithelial cells and nothing else. Other portions of the lung showed the appearances characteristic of a catarrhal pneumonia with here and there areas of interstitial pneumonia.

Spleen somewhat diminished in size, pale, of the usual density; on section, follicles and trabeculæ distinct; pulp considerably diminished in amount. Kidneys somewhat reduced in size, pale, of the usual density; capsule detached with some difficulty, leaving here and there a roughened, granular surface; on section cortex uniformly diminished, surface pale; nothing unusual detected. Ovaries considerably diminished in size; external surfaces irregular, showing numerous cicatricial depressions; density increased; on section show a dense, grayish surface. In the left parovarium was a thin-walled cyst, with clear fluid contents, about the size of a filbert. Beneath the peritonæum, covering the uterus and in the uterine wall, were two dense, grayish tumors about the size of a pea. The stomach, on the lesser curvature, showed two losses of substance of the mucous membrane about five millimetres in diameter extending rather more than half way through the mucosa; one had a black (hæmorrhagic) base. There were also a few superficial hæmorrhagic erosions of mucous membrane. The intestines had nothing remarkable. Liver reduced about one fourth in size, usual density, brown color; on section acini small, centres distinct as brown points. Under the peritonæum at two points were grayish nodules the size of a split, dried pea. Bile ducts pervious. Nothing abnormal observed about the pancreas or aorta. At the sternal end of the cicatrix mentioned above were two nodules, the size of filberts, of grayish color; on section showed a grayish surface with numerous opaque specks.

Post-Mortem Diagnosis. Brown atrophy of heart. Chronic adhesive pleurisy. Chronic catarrhal pneumonia with cavity formation. Chronic interstitial pneumonia. Cancer of the lung. Chronic peribronchitis. Simple atrophy of spleen and kidneys. Parovarian cyst. Fibro-myomata of uterus. Brown atrophy of liver. Cancer of liver (probably). Cancerous nodules over sternum.

It will be seen, therefore, that there was abundant microscopic evidence of cancerous new growth in the lungs. Whether this process had its origin prior to the development of catarrhal pneumonia I am unable to say; but there were no symptoms referable to the lungs until after the exposure to cold and dampness, when the catarrhal process developed in natural sequence.

The cancerous nodules at the sternal end of the cicatrix were plainly attributable to the incomplete removal of the original growth; and this experience teaches, as was remarked above, that it is wiser to remove the integument freely and leave, if necessary, an open wound to close by granulation.

In similar cases I would not again close the wound with catgut sutures, especially where the tension is great; silk or silver wire would be, in my opinion, preferable.

DR. WEBBER then read a paper on

CASES OF LESION OF THE BRAIN CORTEX ATTENDED WITH UNILATERAL SYMPTOMS.

In reply to Dr. Blake the reader said that these unilateral spasms affect one or a few groups of muscles, and are caused by lesion of the cortex due to hæmorrhage, tumor, or meningitis. In the second case there was no previous history, and the unilateral spasms alone would not show the nature of the lesion.

DR. DRAPER asked if the diagnosis of meningeal hæmorrhage made in the first and second cases was not very rare without external violence.

The READER thought it was not so rare as hæmorrhage into the cerebral substance. In this case it seems to have come first in the substance of the brain and spread thence to the meninges. One reason for the diagnosis was that the patient had had long-continued brain symptoms which were suddenly followed by unilateral spasms. The previous history precluded chronic disease of the brain. In some rare cases one might have an abscess or tumor in the brain with no symptoms previous to such an outbreak. As to the examination of the fundus of the eye the reader said that it was not possible to make it in all these cases on account of the spasms. If there was a chronic meningitis on the surface of the hemisphere often no change was found in the eye, but in trouble at the base of the brain or with tumor such an examination would often show definite change in the fundus, and might be of use in making a differential diagnosis. In the first and second cases reported there was a strong retraction of the head, but no opisthotonos; also there was considerable reflex resistance to rectifying that position, but the lesion was not the same in the two cases. In reply to Dr. Williams the reader said that conjugate deviation of the eyes is of limited value as a means of localizing lesions of the brain. This deviation is due to two causes: either paralysis of the external rectus and the opposite internal rectus or spasm of these two muscles. When the deviation is due to paralysis, if the eyes are turned away from the paralyzed limbs, towards the side on which the cerebral lesion has occurred, the lesion must be above the pons; if the deviation is due to spasm and the eyes are turned towards the convulsed limbs, away from the cerebral lesion, the lesion must be above the pons. These forms of conjugate deviation are only of value as localizing symptoms to this limited degree; no opinion can be formed as to the exact seat of the lesion in the hemispheres. If, however, in paralysis the eyes are directed towards the paralyzed side, away from the cerebral lesion, or in convulsions away from the convulsed limbs towards the cerebral lesion, the conjugate deviation indicates that the lesion is in the pons, in the vicinity of or implicating the nucleus of the sixth nerve. In this respect the deviation is of value as locating the seat of disease within very narrow limits.

[1] See page 49 of this number of the JOURNAL.

ANEURISM OF ASCENDING AORTA.

DR. J. G. BLAKE then reported the following case: —

M., aged sixty, carpenter, married; his father died of typhoid, mother of paralysis, and two sisters of phthisis; has one brother living; was intemperate when a young man, but now takes only an occasional drink; no history of syphilis. Three years ago had a pain accompanied by a severe cold in the right side near the nipple and in the right arm. This kept him in bed only a week. First saw the reader about twenty-one months ago, when he complained of cough and pain in the chest and arm, the cough was worse at night and when lying on the affected side, which brought on a choking sensation in the throat. He referred the pain to the junction of the third rib with its cartilage, and on placing the ear over the part a strong pulsation was felt which extended over a surface about as large as a silver dollar. With the stethoscope the sounds were those of a normal heart. No bruit was detected, but there was an absence of respiratory murmur about the pulsating point, and loud bronchial respiration over the upper part of the chest, back and front, with sibilant râles over the lower part. The position of the heart and its sounds were normal, but the heart seemed to strike the chest with abnormal force. Pulse 80. His voice was husky, but he said this was always so. There was no difference in the pulsation of the radial arteries.

About four months ago I examined him again. There was a slight bulging of the chest at the point where the pain was greatest, and the pulsation covered a larger area, but was not so strong as before. There was no bruit over the tumor. Heart sounds normal. The cough was very troublesome. He can lie only on the affected side, for when he turns on the other it brings on the choking feeling. There are signs of effusion in the right pleural cavity, and the face, eyelids, and right arm are much swollen. Urine normal.

Two months before his death the chest was aspirated, in consultation with Dr. Bowditch, and two quarts of clear serum were withdrawn, which gave great relief to the breathing. The swelling of the face and arm diminished rapidly, and almost disappeared. In about three weeks after the tapping the arm again became œdematous, also the face and neck, and the eyelids were so much swelled as to almost close the eyes. Three weeks before his death he expectorated some bloody mucus, and a week later coughed up some three ounces of frothy blood, and four days afterward some blood clots of a very dark color. For a week before death he took no nourishment, partly on account of the difficulty he had in swallowing.

The autopsy, by Dr. E. G. Cutler, showed the following condition: —

The body was extremely pale. Face and upper parts of body quite œdematous. On opening chest there was slight absorption of the cartilages and distal ends of the second, third, and fourth ribs, and of the intercostal muscles between them on the right side. The right pleura contained about two quarts of dark, loose, coagulated blood. The heart, not enlarged, was displaced somewhat towards the left. There was an aneurism of the anterior and right lateral portion of the ascending aorta, beginning half an inch above the aortic valves and ending an inch short of the innominate artery. In size it was about as large as the two fists. Rupture had occurred in the most dependent portion into the right pleural sac. A large laminated clot was found inside the aneurism about two inches in thickness. The wall of the aneurism gradually disappeared and merged into the surrounding tissues, principally the pleura and pericardium. The right lung was collapsed, and occupied a small area; its surface was covered with a few shreds of recent fibrine; the pleura was injected and thickened. The source of the hæmoptysis was not discovered. The other organs were not diseased.

DR. BOWDITCH stated that when he examined the patient on May 8th he found the heart sounds normal; the respiration obscure over a large space in front, to the right of the sternum, and extending from the first to the fifth rib; on full inspiration a few sonorous râles were heard, but no bronchial respiration. In the centre of this space, over the third rib, flat percussion was found, but no bellows murmur there or over the heart. On the back the respiratory murmur was lessened over the entire right side; there was no area of dullness, but a less resonant sound on percussion. On taking a full breath a few sonorous râles were heard at the end of the inspiration. Just below the scapula, on the right side, was a slight prominence.

DR. BLAKE said that after the removal of two quarts of fluid from the chest by aspiration the area of flatness extended from the base of the lung to the middle of the chest in front. On the second tapping the serum was tinged with blood.

ABNORMAL ELASTICITY OF SKIN.

DR. INGALLS then showed a photograph of a man on exhibition in Boston with an abnormal elasticity of the skin. A fold of skin could be taken at the clavicle and raised to the level of the eyes, and when released at once returned to its usual smoothness and position. This had been so from birth, but may have been increased by practice.

ABDOMINAL ANEURISM.

DR. STEVENS briefly mentioned a case of a man of sixty-three years who had an indistinct pulsation below the ensiform cartilage. Last June he went to Swampscott, and while out rowing was suddenly taken with severe pain in the epigastrium. Some eight weeks later the swelling below the cartilage had tripled in size, but there was no more pulsation than would be expected from a tumor lying in contact with the aorta. A diagnosis of malignant disease of the pancreas was made. The patient died suddenly, and at the autopsy an abdominal aneurism, the size of a hen's egg, was found. There was also a new dissecting aneurism of double the size filled with a clot.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

MALFORMED FŒTUS.

DR. GREEN exhibited a drawing of the fœtus, which he had seen in the summer, and gave the following account of the case: The woman, a prostitute, twenty-four years of age, primipara (or said to be so), sustained a severe fall when six weeks pregnant. When seven months pregnant she again fell — on the pave-

ment. She continued her vocation until within five days of labor, which was normal in every respect, resulting in the fœtus, a drawing of which was shown to the Society. It was an example of Förster's monopod (the left leg was wanting), and peropod (as wanting part of the right leg), or, in sum, a pero-monopod. Förster intimates that these deformities are caused very early in pregnancy, from the second to the sixth week. Dr. Green suggested that the accident at the sixth week was perhaps the cause of the abnormity.

TWO CASES OF UTERINE POLYPUS.[1]

DR. MINOT reported the cases and exhibited the specimens.

DR. FORSTER reported the case of an Irishwoman who presented a tumor between the labia. On the Sunday previous to the meeting Dr. Forster removed the mass, which was then external, and attached by a pedicle about five inches in length. Hæmorrhage had existed during four, and protrusion for the last two, months. The tumor in the vagina had acted as a valve, causing the blood to be forced past it. It was exhibited to the Society, was of a flattened oval shape, and measured originally about one and a half inches in its longest diameter.

DR. BAKER asked Dr. Minot if he used scissors or écraseur in the removal of fibroid polypi.

DR. MINOT replied that he always used scissors if possible, and he had never known hæmorrhage to follow; but when the tumor is very large it is sometimes very difficult, or even impossible, to reach the pedicle with scissors, and the écraseur is then very serviceable.

DR. BAKER said that he agreed entirely with Dr. Minot, notwithstanding the fact that the text-books lay so much stress upon the écraseur. The contractile power of the uterus excited by the traction of the polypus in drawing it down is such that hæmorrhage from it is very rare.

DR. ELLIOT stated that he had recently had a case which brought up the question of the cause of hæmorrhage in these cases of uterine fibroid. It was well known that small fibroids contained very few large vessels, and yet they may give rise to terrible hæmorrhages. Looking up the literature he had found very little attention paid to the matter. In the cases mentioned the tumors were taken to Dr. Gannett, who found the investing mucous membrane much thickened, its vessels and glands enlarged, in fine, a condition of hyperplastic endometritis, which is a well-known cause of uterine hæmorrhage. In the case of a middle-aged woman who had been flowing for about fifteen years, at times, and who had had no children, Dr. Elliot found a loss of blood at each menstruation sufficient to saturate sixty or seventy napkins. The patient was seen in consultation with Dr. John Homans; the uterus was dilated, and a small polypus removed. But at the next catamenia the patient flowed about the same as before. After watching the case awhile Dr. Elliot determined to scrape out the uterus. This, after dilatation, was accordingly done, and a hyperplastic endometritis was relieved, so that, at the next menstruation, the flow was in normal amount. Dr. Elliot thought that the rupture of a blood-vessel was very seldom the cause of these hæmorrhages, that the strangulation of the pedicle by uterine contractions causing a state of passive congestion in the tumor was not an infrequent cause, but that this hyperplastic condition of the mucous membrane of either the tumor or the uterus, or of both together, was by far the most common cause.

[1] See page 58 of this number of the JOURNAL.

DERMOID CYST OF THE RIGHT OVARY.

DR. BLAKE read the case. (Paper reserved for revision.) Specimens of hair and teeth from the cyst were exhibited to the Society.

DR. BAKER presented a specimen of hair not unlike in character and origin that just shown by Dr. Blake. The case was of a hospital patient four years ago, and was considered to be one of abscess. The aspirator needle carried up behind the uterus gave a fluid-like pus; a free incision opened the peritoneal cavity, into which the air entered with a good deal of noise. The fluid proved to be not pus, but fat, and upon this circumstance was founded the diagnosis of dermoid cyst. An incision about one inch long was made into the cyst, and its edges united with those of a corresponding incision in the posterior cul-de-sac. Injections were repeatedly made, at one time a mass of hair presented and was removed, later a mass of tissue containing teeth and bone, which was also taken away. Knowing the difficulty of destroying the interior of the cyst, Dr. Baker passed a Sims' speculum *into* it and applied the thermo-cautery to the whole surface. This was four years ago, and the patient has remained well since, with no appearance of any return of the cyst.

DIAGNOSIS AND PATHOLOGY OF DERMOID CYSTS.

DR. GANNETT, in response to a general request, stated that if hair is found the diagnosis is easy enough; it is difficult to get hair through the exploring needle, but fat comes, and this is diagnostic, particularly in the region of the ovary. Dr. Gannett showed two specimens of the fat.

As to the pathology, it was originally supposed, fifty years or more ago, that dermoid cysts represented the results of an ovarian pregnancy, and where such tumors were found post mortem in unmarried women serious aspersions were raised against the moral character of the individual. But as later similar tumors were found in young children before the age of puberty, and further, in the male testicle, it became obvious that some new theory of their origin was necessary.

In later years they have been thought to be congenital; that during fœtal life a portion of embryonic tissue remained in the ovary, and later developed into a dermoid cyst.

Recently Waldeyer has advanced the idea that as any ovarian epithelial cell may become an ovum, so any such cell may develop into one of these tumors.

Dr. Gannett mentioned the fact of the association of dermoid cysts with other tumors of the ovary, he having observed two cases of combination of sarcoma with dermoids, and three cases of dermoid cyst in connection with well-marked cystomata.

THE DELIVERY OF THE SECOND FŒTUS IN LABOR WITH TWINS.

DR. GREEN read the paper.

DR. REYNOLDS said that the statistics quoted in regard to varieties of twin presentations had interested him and had surprised him. The general results differed very materially from those with which he had hitherto been familiar.

Bearing in mind the shape of the pregnant uterus, and the alterations impressed upon it at the time of labor, it had always seemed to him instructive to note

the very great predominance of the longitudinal attitude of the two children. It should be remembered that the folded breech forms the bulky end of the fœtus, that the hard and compact head does not need for its accommodation an equal amount of room. On the other hand the fundus of the uterus and the upper part of the body are proportionally more developed.

In accordance with these facts that arrangement in which both children are placed longitudinally and both heads are in the lower half of the uterus is the more common; a longitudinal attitude with one head at the fundus and one low down comes next in order of frequency, and a similar attitude with both heads at the fundus is comparatively rare; the tendency toward a presentation of the head end of the offspring thus asserting itself in multiple pregnancy as it does in the single form, and as it does also with the multiple pregnancy of the lower animals.

The uterus which has lately undergone distention from twins must often resemble in its want of power, and in its flaccid condition, that of a multipara in whose case successive children have been forced with difficulty through a pelvis somewhat contracted. It may well be conceived that under these circumstances a trunk presentation of the second child may easily develop, as the writer of the present paper has so forcibly urged. Without very convincing testimony it is hard to believe that before labor either one of the living twins can hold a transverse attitude.

Four years ago Dr. Reynolds attended a third pregnancy, when a mother of slight and delicate frame gave birth to two large males. Both heads were at the fundus; over that which lay at the left angle such intense discomfort was felt for many days before birth that no change of position could be tolerated, the patient lying all the time on one side, "unable to move," and in pitiful distress.

In the light of some recent contributions to the study of the mechanism of labor the view which the paper takes, that the point at which the vertebral column of the fœtus meets the head is the main factor, or even the only agent, in bringing about flexion of the head or its extension, is perhaps somewhat too absolute.

DR. GREEN said that if the uterus were emptied too quickly there would be increased danger of post-partum hæmorrhage. He also considered the dorsal position as occasioning greater danger to the perinæum upon the descent of the fœtus.

DR. BLAKE said that he had considerable experience with cases of twin birth. He had seldom found the membranes of the second child ruptured, and it had been his custom to wait from ten to twenty minutes after the birth of the first child and then perform the rupture. He had never had any difficulty with cases of twins; never had had to turn the child. In natural labors he preferred the dorsal position of the mother.

DR. LYMAN asked Dr. Green if he thought there were greater danger of rupture of the perinæum with the patient lying on her back than when on her side. He thought the difference in results between Paris and London, where these different positions were in vogue, did not sustain any such view.

DR. GREEN replied that the weight of the head on the perinæum would be greater in the dorsal position.

DR. RICHARDSON asked if the weight of the head was any factor whatever in the cause of ruptured perinæum.

DR. GREEN said that he had accepted the statement of books, and had had regard to the custom in Germany. Rupture no doubt depended in great measure upon the condition of the perinæum.

DR. RICHARDSON stated that in the few cases of twins which he had looked up the great majority of bad cases were due to interference, and especially to attempts to hurry on the labor.

DR. GREEN explained that he did not advise interference but avoidance; during the period of uterine inactivity he would keep the hand on the uterus in order to maintain a correct position.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

DISCUSSION ON NERVOUS PROSTRATION.

DECEMBER 19, 1883. DR. MILLS, in opening the discussion on Dr. Bartholow's paper,[1] by request of the chair, said: I understand that Dr. Bartholow denies that a disease exists, primarily nervous in origin, which can be called neurasthenia. He classes all cases so called under two heads, congestive and anæmic, and holds that the symptoms presented are chiefly reflex effects of digestive or other visceral troubles. I have no doubt that many cases are to be thus explained, but we have others in which the cerebral condition is primary. In cases with the symptoms as detailed in the paper we may, perhaps, clearly ascribe them to the causes and conditions referred to by Dr. Bartholow, but other cases may be explained in a different manner.

In individuals whose higher ganglionic centres are so constituted, from bad inheritance or poor training, or both, that they cannot bear much strain, when subjected to this strain these centres exhaust. We have certain functions called organic functions, respiration, vaso-motor action, etc., with centres in medulla oblongata and spinal cord. These functions must be maintained as long as the individual exists. Their centres must be nourished and sustained in a uniform way. Presiding over automatic movements, they must be kept in the highest tone, must have good blood and plenty of it. It is a principle brought out in the paper that local diversion of blood to any one organ or part will take it from other organs or parts; and we may, in accordance with this, have the higher brain diverting blood from the lower, or lower brain from the higher. We have *nervous* symptoms, the result of this overstrain of nerve centres, and the disturbance of the equilibrium of the circulation, thereby brought about.

I am inclined to differ from Dr. Bartholow and agree with Dr. Beard as to the propriety of the term "American disease." The social and business exigencies in this country are different, are more taxing than in Europe. In England, for instance, men become mature and enter public life at later periods than here. In France the difference is not so great, but the more absolute division of society into grades and castes prevents too fierce a struggle for high position. Here every man has the chance to rise to the highest position, and men enter especially political life in youth. Americans are not trained for special lines of life work. They often attempt work too high for their mental powers and break down.

DR. TYSON: I have many times asked myself the question, "What is nervous prostration?" The an-

[1] See page 53 of this number of the JOURNAL.

swer was always, "It is not a nervous disease, certainly not an organic nervous disease, and probably not a functional one. It is rather a condition of muscular fatigue, and it may be nervous fatigue. Most of the cases are accompanied by digestive derangements, which are responsible for many of the symptoms, most of which are reflex." At the same time I admit that some of the symptoms are puzzling, and not easily explained. Among these is the pain in the back of the head, often referred to as the result of "nerve tire," and sometimes regarded as an important indication of cerebral disorder, which it is not. In women uterine derangement is often responsible for the complex symptoms known as nervous prostration.

The point, however, that attracted me in the paper read was allusion to the condition of the urine in one of the cases. It was described as dark-brown, of high specific gravity, containing a trace of sugar. I have seen such cases, and think it not unlikely that the apparent sugar reaction is really due to uric acid, which is often abundantly present in these urines of deranged digestion. If we get rid of the excess of uric acid by allowing it to precipitate spontaneously, or precipitate it by the addition of an acid, the sugar reaction with the copper tests does not take place. Other characters of the urine, particularly its dark color and scantiness, are not usual to sugar-containing urine.

DR. ESKRIDGE: The most important point in the subject is whether the condition called neurasthenia is primarily a nervous disorder or a disturbance in other parts of the body. I would have been better pleased if Dr. Mills had elaborated more thoroughly his statements as to the organic functions. He said these functions must be well nourished, and that failure in them is due to failure in the upper nervous system. I would have liked if he had gone further in his explanation. Is this failure due to disturbance in the brain and upper portion of spinal cord primarily, or to failure in other parts of the body? Those who have paid attention to this subject say that break-down does not occur unconnected with either worry or vice. I have never seen a case from mental overwork alone. In five cases of neurasthenia of which I have notes one was from sexual excess; two from worry connected with family troubles; another from alcoholic excess with sexual vices; and the fifth from sunstroke followed by oversexual indulgences. In the last case it seemed as if the brain was primarily at fault. It appears to me that nervous prostration, so called, is a depressed condition of the whole system, the trouble manifesting itself as a general nervous condition secondarily after organs other than the brain have been primarily affected. The therapeutics also favor this view because the cases are benefited not by agents addressed to the nervous system alone, but by hygienic and tonic measures.

DR. GLASGOW: I have come to regard these cases as not nervous in origin, but as largely due to digestive troubles. They are cured by attention to the disordered functions. I have known a short residence in Atlantic City, without any medical treatment, to suffice for a cure.

DR. BARTHOLOW, in closing the discussion, said: The great question is, Is neurasthenia functional or does it arise from organic change in the nervous system? I maintain that it is largely reflex and frequently from gastric disturbance. Neurasthenia in women is associated with an anæmic condition and ovarian and uterine disorders. They are pale and weak, and if they are subjected to any moral or mental trouble give way, but if they are well nourished sustain any kind of shocks without suffering in health.

In regard to the term "American disease," and to the claim that the peculiar conditions of American life are causative of neurasthenia, it will suffice to say that in some of the European states a higher grade of education is maintained than in this country. In Prussia, for instance, every one is taught to read; education is more general than in Massachusetts. The struggle to maintain existence, and hence the demands on the brain, are severer than here, and although neurasthenia is said to be uncommon there are diseases similar to that called nervous exhaustion in this country arising from similar causes.

Worry has been mentioned as a cause of nervous exhaustion. Now worry hurts a man just in proportion to his condition. If he is in good health or phlegmatic in temperament the worry may be well borne, but if he is out of health worry will have a powerful effect on the nervous system. I do not deny that various causes may produce brain disease, but I deny that the so-called neurasthenia is due to an organic lesion of the nervous system. I maintain that it is part of a morbid complexus, a reflex condition, in large part, of maladies situated in the stomach, the liver, the uterus, or other organs.

Recent Literature.

The Dissector's Manual. By G. W. BRUCE-CLARKE, F. R. C. S., and CHARLES BARRETT LOCKWOOD, F. R. C. S. Philadelphia: Henry C. Lea's Son & Co. 1883.

This is a very excellent manual for the use of the student who desires to learn anatomy. It has the merit of not being in the least a compendium. It does not, for instance, give the origins and insertions of muscles, but it states what is to be found in each region, and tells how to find it. The authors insist that dissecting a part is not learning it, but that the student should go over the structures that he has exposed, comparing them with the accounts in the text-books of descriptive anatomy. The methods of demonstration seem to us very satisfactory, and we are especially glad that much attention is given to the dissection and study of the viscera. There are many wood-cuts, which for the most part are good and instructive, but we must say that the diagrams of the front and back of the body that make the frontispiece are extremely distorted and inaccurate. There is a very interesting chapter at the end on "dissecting questions," which form a part of some of the examinations in England. The student is asked to tell how any particular structure may be exposed, enumerating the parts that are exposed or divided in reaching it. The book, which is of the same series as Mr. Treves's Applied Anatomy, is neat and convenient. We are glad to recommend it.

T. D.

— "Boss, hab you gat any dem confound cunfortic pills?" "Yes. Do you want them plain or coated?" "Dunno. I want dem ones dat's whitewashed." He got 'em. — *Texas Siftings.*

Medical and Surgical Journal.

THURSDAY, JANUARY 17, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

STATE PROSECUTIONS FOR ADULTERATED DRUGS.

THE daily papers of this city recently published in full the correspondence between the Boston Druggists' Association and the Health Committee of the State Board charged with executing the law against adulteration of drugs, a correspondence referred to in an editorial article of our issue of December 13th last. We believe the following statements bearing on this correspondence are correct, and should be kept in mind should any attempt be made to induce the present legislature of Massachusetts to repeal or render inoperative a law, more necessary than we had previously supposed, for the protection of the public at large and of the medical profession in the discharge of its duties to the public.

In each of the six prosecutions for adulterated drugs which have been made by the Massachusetts Board of Health, Lunacy, and Charity the adulteration has been proved.

In each case the drug was shown to be more than thirty per cent. below the pharmacopœial standard, about one fourth, one half, or two thirds being the most common proportions.

In no case was prosecution made until after a second violation of the law had been detected, and in all cases but one in the same drug. In that one case, however, there had been two violations in regard to another drug. The drugs were in every instance prepared by the firm proceeded against, and were sold either by a member of the firm or else in his immediate presence, and with his knowledge and consent.

In cases of adulterated drugs not prepared by the vendors, warning notices thereof, and not prosecutions, have followed the first detected violations of the statute.

ANNUAL REPORTS OF THE PRESIDENT AND TREASURER OF HARVARD UNIVERSITY, 1882–1883.

THE portion of these annual reports which particularly concerns the medical profession is that devoted to the Medical School and contributed by its dean. The completion of the new building, at a total expense of $321,415, of which possession was finally taken in October, has been previously noticed at length in our columns.

The whole number of students in attendance during the year was 240; during the first term 234; during the second term 219. Of these 116 had a literary or scientific degree. There were eighty-five applicants for the degree of Doctor of Medicine, of whom nine were rejected. Seventy received the degree of M. D. after a three years' course of study; six received the degree of M. D. after a four years' course; of these six, four received in addition the degree of A. M., two of these *cum laude*. The Fourth Class was composed of ten students, four of whom postponed graduation in order to become candidates for hospital appointments.

The results of the examinations for admission to the School are given in the following table: —

			Physics.	Latin.	English.	Elective.	Rejected.
1883.	June.	Offered.	25	25	25	25	3
		Conditioned.	8	8	5	3	
	Sept.	Offered.	18	18	18	18	1
		Conditioned.	2	9	4	2	

An elaborate table on page 99 of the report, whose length forbids reproduction, gives statistics of rejection at examinations in the different subjects studied by each class during the last four years. Those curious in the matter are referred to the original.

The following table, as last year, is given by the dean to show the increasing recognition of the value of the opportunities offered by the School for obtaining a medical education: —

NUMBER OF TERMS SPENT AT THE SCHOOL BY GRADUATES.

	1874.	1875.	1876.	1877.	1878.	1879.	1880.	1881.	1882.	1883.
Spent six terms.	22	14 47%	25 69%	40 65%	41 85%	62 88%	39 80%	49 81%	79 91%	67 88%
Spent five terms.	2	7	5 1%	9	4	2 2%	1 2%	6 10%	2 2%	4 5%
Spent four terms.	6	6	4 11%	8	3	3 4%	4 8%	4 6%	4 4%	4 5%
Spent three terms.	5	0	2 5%	1	0	2 2%	0	1 1%	0	1 1%
Spent two terms.	3	3 10%	0	3	0	1 1%	1 2%	0	1 1%	0
Total graduated.	38	30	36	61	48	70	45	60	86	76

In the Dental School the number of students was twenty-six.

The School of Veterinary Medicine submits its first annual report. At the examinations held in June and September eleven candidates presented themselves for admission, of whom two were rejected. With the new Veterinary Hospital on Village Street and the accom-

modations offered at the Bussey Farm advantages for the study of comparative anatomy, physiology, and pathology will be gradually developed.

In the main body of the report the President insists upon the views previously expressed by the Faculty of the college in regard to intercollegiate contests in athletic sports, namely, that they demand further regulation by agreement between the colleges whose students take part in them, and that this can be done without discouraging the promotion of physical exercise and manly sports among college students. The department of hygiene and physical training is reported as being in general in good condition, and the Hemenway Gymnasium as being each year more and more patronized.

The department of the university which seems to cause its President the least satisfaction is the Board of Overseers, which he finds altogether too venerable and conservative, the average age of the elected members being, he calculates, fifty-seven years.

Although having but a possibly indirect relation to medical education, we cannot forbear quoting in full the closing sentences of his report where expression is given to the President's dissatisfaction with this venerable Board: "When the Act of 1865 gave to the alumni the power of electing the overseers it was imagined the electors, the larger part of whom would be young men, might choose a youthful or inexperienced Board. The actual result has been quite the reverse. Only one of the present Board is under forty, only ten of the thirty elected members are under fifty, and the average age of the elected members is fifty-seven. No member of the Board graduated in arts later than 1866, and on an average the Board may be said to have graduated more than thirty-five years ago, at a time when the university was very unlike the institution of to-day. Such elderly men may be distinguished representatives of the alumni, and may, perhaps, be in a position to enjoy the advantage of advice from sons or grandsons now or recently members of the university, but their personal recollections of college life are less serviceable to them as university legislators than the recollections of much younger men would be."

One of the most important objects in all schemes of representative government — the independence of the legislative from the executive departments — has been accomplished with the existing Board of Overseers. Whether the interests of the university would be better served by younger or more pliant overseers is for each elector to decide for himself.

— A woman was fined forty-eight francs in one of the departments, says the French correspondent of the *Medical Press*, for having performed the Cæsarean operation on a woman who died suddenly in the first stage of labor. The operation was performed at the instigation of the priest, who wanted to baptize the child. The instrument used was a razor, and there appeared to have been no attempt made to preserve the child alive, as, after baptism, it was replaced. The incident created some scandal in the country.

QUARANTINE AND HEALTH, CHARITY AND LUNACY IN THE CITY AND STATE OF NEW YORK.

IN his last annual message the Governor of New York gives the following statistics in regard to the insane in that State: —

State Lunatic Asylum at Utica	600 patients.
Hudson River State Hospital	306 patients.
State Homœopathic Asylum	260 patients.
Buffalo State Asylum	329 patients.
Willard Asylum (chronic insane)	1740 patients.
Binghamton Asylum (chronic insane)	412 patients.
County poor-houses and asylums	1867 patients.
City almshouses and asylums	5010 patients.
In private asylums	493 patients.
Asylum for Insane Criminals	144 patients.
Asylum for Insane Emigrants	109 patients.
Total	11,270 patients.

Of this number 5015 are males, and 6255 females, and the total number given is 827 in excess of the number of insane reported for the previous year. We should like to have had the proportion of foreign and native born among these insane.

The following quotations are from the portions of the Governor's message referring to very important questions touching the quarantine and Health Officer of the port of New York: "In July, 1881, the Senate appointed a committee to investigate and ascertain the emoluments, and to examine into the administration, of the Health Officer, with a view of making the Quarantine Department self-sustaining, and framing such laws as may be of public interest. In concluding their report the committee state that they 'cannot refrain from expressing the opinion that the revenues of the Health Officer of the port of New York are out of all proportion to the professional skill and labor required to properly fill the office. Exceeding, as they do, the salary of any of the State officers, the Governor included, they constitute an anomaly in the administration of the Commonwealth which is uncalled for, inexcusable, and ought not to be permitted to continue.' Another fact appears in the evidence taken by the committee which is not referred to in their report. The present incumbent of the Health Office testified that in the year 1880 he paid between $9000 and $10,000 as a voluntary contribution to the party of which he was a member for political purposes. . . . In my judgment the Health Officer should be attached to the quarantine establishment, and be paid a fair salary, which, as well as the salaries of the other parties in charge of the department, and the cost of maintaining the buildings and property of the State used in connection therewith, should be met by fees and charges collected for services performed, which fees and charges should be fixed at no higher rate than is necessary to meet such expenses. The inauguration of such a system, it is believed, would insure an efficient administration in this important department, relieve the tax-payers of the State from present burdens, and subserve the interests of the commerce of the port."

In connection with the quarantine administration of the port the administration of the Health Department

of the city of New York naturally invites attention. In the former a reorganization is suggested, in the latter it has been effected.

The estimate for the expenses of the Board of Health of the City of New York for the year 1884 was $540,799, but the appropriation was reduced to $402,775 by the Board of Estimate and Apportionment. The service of the Board was reorganized on the 1st of January, and hereafter the Sanitary Bureau will consist of seven divisions. The first will include one chief inspector and ten assistant inspectors, and during the summer months fifty additional assistant inspectors are to be added. To the second division will be referred all matters relating to adulterations of food and drink, and to offensive trades, and it will consist of one chief inspector, two special inspectors for offensive trades, and for tea, coffee, etc., one chemist, four milk inspectors, and six fruit inspectors (for three months each). The third division, which will have charge of complaints about sidewalks, etc., and the enforcement of ordinances, will include thirty sanitary policemen. And the fourth division will consist of the inspectors of vaccination and disinfection and their assistants. The fifth division will be in charge of the hospitals and the steamboat of the department. In the sixth division there will be one chief inspector, ten inspectors, and three clerks. And the Bureau of Vital Statistics, having charge of the records of births, deaths, and marriages, and of the granting of burial permits, is to constitute the seventh division. The whole will be under the charge of a sanitary superintendent, who will also perform the duties of register of records, and an assistant sanitary superintendent, who will also be chief medical officer in charge of the fifth division. The Board of Estimate and Apportionment reduced the appropriation for the Department of Charities and Correction from $2,149,627.60, the amount asked for, to $1,774,105.10.

MEDICAL NOTES.

— We have just announced that the publication of the *Archives of Medicine* was to be suspended. We take pleasure in announcing that the publication, instead of being suspended as was at first announced, will be continued on the same general plan as that followed during the past six years.

— The new year has brought to us *The Æsculapian*, a new monthly journal of medicine and surgery, edited by Edward J. Bermingham, M. D., and published by Bermingham & Co., New York.

— An English physician states that he has known one of his prescriptions to be made up without his order to his patient more than three hundred times. He was paid for only one prescription.

— The *Waltham Backwoodsman*, a paper published to advocate the retention of the town form of government in Waltham, announces in its prospectus that "it will copy after its esteemed contemporaries in everything except blowing for a city government and publishing Warner's Safe Kidney Cure, Bull's Cough Syrup, and Lydia Pinkham's portrait;" in which matter it sets an example to certain so-called religious papers.

— The effectual separation of Milk and Water Streets by the Old South Church is supposed by certain antiquarians to be typical of the sentiments of the early inhabitants of Boston in regard to the mixture of two important articles of domestic consumption. The facts revealed by the milk analyst of the Massachusetts Health Board seem to show that the meandering of Spring Lane between the two streets left open the way for complications, as out of every ten specimens of milk examined nine showed an improper aqueous admixture.

— During the year 1883 there were reported to the Boston police 333 cases of runaway children, 89 of lost children, 251 of persons missing, and 23 of persons found dead. There have been reported to the department during the year 423 cases of sudden deaths, as follows: Murders, 5; suicides, 31; fatal accidents, 123; found drowned, 50; found dead, 27; burned to death, 7; other causes, 180.

NEW YORK.

— In his annual message Mayor Low, of Brooklyn, says, in regard to the water supply of that city, that there is literally no margin above its needs at present, and recommends the immediate enlargement of the distributing reservoir at Ridgewood to double its present size. In his opinion steps ought to be taken to secure an increase of 20,000,000 gallons daily, and eventually a supply of at least 100,000,000 gallons daily. The cost of this work, which would be distributed over several years, is estimated at about $4,500,000. He also recommends the appropriation of $1,500,000 or $2,000,000 to remedy the existing defects of the sewage system of the city.

— On the 9th of January a conference was held at the rooms of the Brooklyn Board of Health for the purpose of discussing the question of the prevention of contagious pleuro-pneumonia in cattle, at which representatives of the New York, Brooklyn, and State Boards of Health and of the United States Treasury Cattle Commission as well as a number of physicians from different parts of the State were present. The chairman, Dr. Raymond, Health Commissioner of Brooklyn, read a paper by Dr. McLean advocating inoculation, and a free discussion followed. At the conclusion of the debate Professor Law, of the Cattle Commission, presented a set of resolutions to the effect that Congress should be petitioned to appropriate a sufficient amount of money to stamp out contagious pleuro-pneumonia by providing for the appointment of a number of veterinaries to inspect all herds in infected districts, to indemnify owners for all cattle slaughtered by the government, and to forbid the movement of all cattle out of any infected State which will not take measures to stamp out the disease. The resolutions were adopted, and a committee was appointed to present them at a conference to be held on the same subject on the following day in Washington.

— Mr. Charles Lanier, treasurer of the Hospital Saturday and Sunday Association, announces that up

to January 9th the contributions, so far as reported, amounted to $22,532.85.

— The will of Mr. Julius Hallgarten, a wealthy New York banker, who died recently in Switzerland, provides for a large number of charitable requests, among which are $50,000 each to the University of the City of New York and Dartmouth College, and $10,000 to Mount Sinai Hospital, New York.

— A committee composed of some of the leading physicians of New York, Boston, Philadelphia, Chicago, and other cities, of which Dr. Fordyce Barker is chairman, and Dr. George F. Shrady, editor of the *Medical Record*, secretary, have issued an appeal for contributions towards the erection of a monument in honor of the late Dr. J. Marion Sims.

— At a meeting of the Medico-Legal Society held January 9th the recently elected officers were installed. In his inaugural address the President, Mr. Clark Bell, stated that during the past year the membership had been increased from 267 to 314, of which number 147 were physicians and 154 lawyers. The draft of a bill was submitted which provides for the appointment of medical examiners throughout the State whose duty it shall be to pass upon the mental condition of persons before the courts in regard to whose sanity there is any question. A special committee was instructed to secure the passage of the bill by the Legislature if possible.

— At a meeting of the Society of Medical Jurisprudence and State Medicine held January 10th Dr. E. C. Spitzka read a paper on the Execution of an Insane Murderer. The murderer referred to was Graves, recently executed at Newark, N. J., in whose behalf the Governor and Court of Pardons refused to interfere. He said it was the most melancholy case of an insane criminal that had ever come to his knowledge, seven medical experts having pronounced Graves insane, and the post-mortem examination having fully substantiated their opinions.

PHILADELPHIA.

— The annual meeting of the Philadelphia County Medical Society for the election of officers and new members was held January 2d, when the following officers were elected for the ensuing year: William M. Welch, President (second term); William S. Forbes and S. R. Knight, Vice-Presidents; Henry Leffmann, Recording and Reporting Secretary; M. S. French, Corresponding Secretary; L. K. Baldwin, Treasurer; C. M. Seltzer, Librarian; H. St. Clair Ash, Censor. At this meeting there were among the candidates to be balloted for the names of two prominent women physicians connected with the Women's Medical College in this city. They failed to get the required two-thirds vote.

— A very full meeting of the College of Physicians was held January 3d, to listen to the address of the retiring President, Prof. Alfred Stillé, who devoted his time principally to a historical sketch of the development and growth of the library, which now contains over 26,000 volumes. Papers were read at the same meeting by Dr. Harrison Allen, on the Chronic Nasal Catarrh of Children, by Dr. Horatio C. Wood, on the Clinical Aspects of Brain Syphilis, and by Dr. J. Cheston Morris, on an interesting case with specimens.

The college is now in a prosperous condition, and every department shows new and increased interest and activity. A fund has been started for enlarging the building by adding another floor, one of the Fellows contributing a thousand dollars to this object, and has promised further assistance if needed.

The Nurse Registry Bureau had a successful year, and has contributed a considerable amount to the uses of the library. It is becoming each year better known and more generally used, until it is now considered a necessity.

— At the Conversational meeting of November 9th of the County Medical Society, Dr. John Ashhurst, Jr., presented a communication on the Treatment of Chancroid and Syphilis; discussion upon this paper being opened by Dr. J. William White. A large attendance of the members was had, and a general discussion held; full of interest, but, as might be inferred from the subject, containing little that was new.

— The Alumni Association of the Jefferson Medical College will give a reception to Prof. Theophilus Parvin on the 28th of January at the St. George Hotel, in this city. A large attendance is expected, and the reception will undoubtedly constitute one of the medical events of the winter.

— At the Pennsylvania Hospital Dr. J. M. Da Costa is using hypodermic injections of iron for anæmia, in a case of combined malarial toxæmia and lardaceous disease of the viscera, including the intestinal glands. To the other solutions for this purpose he prefers a double salt produced by the addition of pyrophosphate of iron to a solution of citrate of sodium. Two grains of the salt, in this form, are given every day, varying the points of puncture, but generally administering it under the skin of the extremities; in this form no abscesses have been observed. With other solutions of iron, including dialysed iron, abscesses were quite common even with every precaution as to the cleanliness of the syringe. In a case last winter of idiopathic anæmia (pernicious?) these injections not only arrested the patient in a downward course, but actually worked such a change that his strength and appetite returned and he was afterwards discharged in good health. This case is not called pernicious anæmia because the patient did not die; but if an opinion could be based upon the previous course of the disease, and his chlorotic condition at the time of the change in his treatment, no other diagnosis and no other prognosis would have been entertained than that mentioned by any ordinary observer.

— The leading druggists of this city becoming disgusted with the patent medicine traffic have decided after the 1st inst., not to deal in those proprietary medicines which are sold as merchandise to non-medical dealers. It is now, and has been for some time, indeed, considered very bad "tone" for a scientific pharmacist to exhibit patent medicines in show cases, or have their lying placards hung up in the store; much less would one of our principal apothecaries think of as-

suming the responsibility of recommending articles of whose composition he is ignorant. The druggists all over the country are alive to this evil, which has grown to such proportions as to seriously threaten the future of legitimate pharmacy. Fortunately the public has acquired a healthy skepticism with regard to advertisements of panaceas, even when they appear in religious papers, and endorsed by clergymen and members of Congress. How soon will this country attain to the degree of civilization of Japan, and appoint a government commission to examine all patent medicines that are offered for sale, and publish the formula upon each package sold. We do it with guano, why not with cough syrups?

— The recent annual report of the Library Committee of the College of Physicians showed that there have been added to the library this year 2186 volumes, 2107 pamphlets, 2862 numbers of journals.

The total number of volumes now in the library is 26,359. For the ensuing year the library will be kept open, except on Sundays and legal holidays, from ten o'clock A. M. to five P. M.

There are in the collection 3381 duplicates, and particular attention was called to this fact, inasmuch as it affords a rare opportunity to other libraries of augmenting their list at comparatively small expense.

The report of the Committee on the Directory for Nurses showed that the

Number of nurses registered December 1, 1882		209
Added during the year	104	
Lost by striking from roll	6	
Lost by withdrawal	4	10
Net gain		94
Present number		303

Total number of nurses furnished during the year 733; an average per month of 61, as against 49 for last year.

Largest number (February)	84
Smallest number (August)	34
Sent outside of the city, but within the State	63
Sent to other States	59
Wet nurses furnished	17
Of registered nurses, there are males	39
Of registered nurses, there are females	264
Graduates of training schools	60
Non-graduates	243

The amount given to the library during the last year was $200, and for the present year $300. Many physicians take great trouble and waste much valuable time in hunting up nurses personally; or, having obtained a good nurse through the Directory, they transfer her from one patient to another directly, instead of through the Directory. Were they to use the Directory they would obtain the *same* nurses and add to the income of the Directory, and so to the appropriation to the library.

It is the desire of the committee to make the Directory also a bureau for all needed information for the sick; and they have in contemplation measures by which if any one desires to obtain boarding in the country or at the sea-side for cases of whooping-cough, or for recent cases of measles, scarlet fever, or diphtheria, and for information concerning all appliances for the sick, such as invalid chairs, wheel and other crutches, bed-rests, fracture, water, or air beds, etc., he may obtain the object he seeks at the Directory.

Correspondence.

"SEA-WATER" (?) AND SALT IN THE STREETS.

MR. EDITOR, — Will you permit me to ask "Nesciens" when and where any Board of Health or any individual ever protested, or had the chance to protest, against watering the streets with "*sea* water"? Will "Nesciens" also tell us whether he can imagine any harm in carting back upon and evaporating from the surface of the streets the *sewage* which has at great expense been carried off beneath those very streets?

Will he further tell us whether, should the streets at any time become dry after the dust became thoroughly saline from pure sea-water, such saline particles would, more than ordinary dust, produce agreeable sensations and healthful results when applied to the mucous membranes of eyes, nose, and air passages by the unrelenting zephyrs?

Will he also tell us in what city it is that horses' feet "do not ordinarily come near the rails"? I had supposed that in the vicinity of the rails was just where horses' feet do come, especially of the pair of horses which precede between the rails each horse car that runs upon the rails, and that the mingling of salt and ice produced an intensely cold and corrosive mixture, which not only must be directly injurious and uncomfortable to the feet of the horses, but must produce a temporary shrinkage of the shoes and a permanent rusting of the nails that could not be advantageous.

QUÆRENS.

CAMBRIDGE, *January* 12, 1884.

SEA-WATER FOR STREETS; SALT ON STREET RAILWAYS.

BOSTON, *January* 13, 1884.

MR. EDITOR, — Permit me to answer the questions in your last issue of the JOURNAL by "Nesciens" on Sea-Water for Streets, Salt on Street Railways. He asks four different questions concerning things which he seems to think are naturally innocent, wonders that boards of health denounce them, and that the courts are besieged to put a stop to such proceedings.

First and *second*. "What is there injurious to health in watering streets with sea-water or putting salt on street railway tracks?"

Third. After admitting the great cold produced upon the horses' feet by the mixture of salt and snow, and the irritation to their "sore or tender hoofs," he asks, "What has it to do with the public health?"

Fourth. "How can the public health be injured by watering the streets with sea-water in summer (repetition of question two) or by running off into drains and cesspools in winter of salted ice-water slightly ferrated?" etc.

Although in a position to hear such complaints if they were made, I have never before heard that any one objected to the watering of streets in summer with *clean* sea-water or of running off the abominable salted slush from the streets in winter. Boards of health

and others who have considered the matter prefer the salt water for streets in summer on account of being cheaper than fresh water, doing better service, and being a good antiseptic.

I don't know that any one claims any immediate connection between the sufferings of our dumb animals who draw us over the streets with sore and tender feet and the public health. I hope the allusion to the poor horse by Nesciens was not meant to be as *cold*-hearted as it seems.

The real question here is the salting of railroad tracks and its connection with the public health.

Whenever the railroad tracks are salted nearly the whole street becomes affected through the use of the snow plow at the intersection of streets and large crossings. Where the most travel is found the most salt is used, and the worst condition of things exists. The salt and snow or ice make a freezing-mixture in which no one can long stand or walk with ordinary protection without loss of comfort and danger to his health. It clings to the feet and cannot be avoided when leaving a car or crossing a street. When the temperature rises and thawing begins the streets are turned into ponds of salted slush too quickly to be cared for, and people have to go with wet and cold feet through the streets on account of salted car tracks. Do I need to add that cold and wet feet caused by the salt and snow mixture are prejudicial to the health and comfort of our citizens, or that most people will see the want of similarity between a "dip into the ocean itself for health's sake," followed by the well cared-for reaction, and walking about the streets with cold feet in a freezing-mixture of salt and snow?

I am compelled to take issue with "Nesciens" as to the innocence of salted snow in our streets, and claim that the health and comfort of our citizens are disturbed by it, and that our Boards of Health are looked to for protection against this evil by thousands of persons who have denounced it.

The courts have not been "besieged to stop such proceedings," but have been properly applied to when necessary in the enforcement of the health order. The "Boards of Health" have not found it difficult to furnish the necessary evidence to convict the violators of the salt order, and anticipate none in the future.

S. H. D.

Miscellany.

OBITUARIES. DR. THOMAS W. PERRY. DR. GEORGE C. LAWRENCE.

DR. THOMAS W. PERRY, a member of the Rhode Island Medical Society, and for many years a practitioner in Providence, died suddenly in this city, on the 5th instant, in the office of Dr. Bowditch, of heart disease. He was born in Hopkinton, R. I., was the son of a physician, with whom he began his medical studies, afterwards continuing them in the office of Dr. Bowen, of Connecticut, and in a school in New York. He entered practice at Wilkinsonville, now Putnam, Conn., but afterward removed to Central Falls, R. I., and subsequently to Providence, where he has had an extensive and successful practice. Dr. Perry faithfully served the country for nine months during the rebellion as surgeon of the Eleventh Regiment Rhode Island Volunteers. He was sixty years of age.

GEORGE CARLISLE LAWRENCE, M. D., a member oft he Massachusetts Medical Society, and one of the oldest and most prominent physicians of Berkshire County, died suddenly on the evening of the 6th inst., at North Adams, of typhoid fever, after an illness of a few days.

JOINT STANDING COMMITTEE ON PUBLIC HEALTH OF MASSACHUSETTS LEGISLATURE.

THE following are the names and occupations of the members of the Joint Standing Committee on Public Health of the Massachusetts Legislature: Messrs. Burden of Bristol, physician (Massachusetts Medical Society); Hodges, of Norfolk, banker, and Campbell, of Suffolk, coal-dealer, on the part of the Senate; Messrs. Bowker, of Boston, manufacturing chemist; Stowe, of Fall River, physician; Hastings, of Warren, physician (Massachusetts Medical Society); Murdock, of Leicester, manufacturer (but at one time a student of medicine); Burditt, of Clinton, apothecary; Hazen, of Shirley, farmer; Cutler, of Brimfield, life-insurance agent, and Peakes, of Georgetown, leather business, on the part of the House.

THE BEQUEST OF THE LATE DR. CALVIN ELLIS.

UNDER the will of the late Dr. Calvin Ellis we understand that Harvard University becomes residuary legatee of his property, which is quite considerable, under certain contingencies. The income is to be devoted to the support of scholarships and the payment of professors' salaries in the Medical School.

HYSTERICAL PSEUDO-PHTHISIS.

THE *Practitioner* (December, 1883) reproduces from *Centralblatt für Gynäcologie* (September 8th) an article by Dr. Fabre describing a condition simulating phthisis often found in young women suffering from chlorosis and hysteria. There is a cough, with expectoration, and even spitting of blood. Physical examination reveals dullness at the apex (usually on the right side), feeble respiration, and occasional râles. The author regards these symptoms as due to a vaso-motor disturbance exciting a pulmonary congestion. Other organs may also be subject to functional disturbances. Obstinate anorexia, gastric pain, occasionally diarrhœa, but more frequently constipation, are not seldom present. The pulse is weak and frequent, like that of fever, although the temperature may be normal. Sometimes, however, there is elevated temperature, but it is only transitory, and regular evening exacerbations are never observed. The expectoration is not purulent, but may be mixed with blood. While in true phthisis there is emaciation, in these cases the patients often increase in weight. Sweating, as a rule, is not met with.

The differential diagnosis is often difficult, and the author relates that cases have not infrequently occurred in which a diagnosis of pulmonary consumption was made, but the patient nevertheless recovered. The condition may exist without material improvement for months, or even years.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 5, 1884.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				The Principal Infectious Diseases.	Consumption.	Typhoid Fever.	Diphtheria and Croup.	Scarlet Fever.

Deaths reported 2783 (no report from Buffalo): under five years of age, 989: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 496, lung diseases 547, consumption 388, diphtheria and croup 200, scarlet fever 67, typhoid fever 55, diarrhœal diseases 46, measles 44, erysipelas 19, malarial fever 19, whooping-cough 16, cerebro-spinal meningitis 13, puerperal fever 12, small-pox four, typhus fever one. From *diarrhœal diseases*, New York 12, New Orleans 10, Brooklyn and Baltimore four each, Boston five, Philadelphia and Chicago three each, Cincinnati, Providence, Nashville, New Bedford, and Shrewsbury one each. From *measles*, Baltimore 13, New York 11, District of Columbia 10, Brooklyn six, Philadelphia two, Milwaukee and Providence one each. From *erysipelas*, Chicago five, New York and Brooklyn three each, Philadelphia and Boston two each, New Orleans, Charleston, Springfield, and Ashland one each. From *malarial fevers*, New Orleans five, New York four, Chicago three, Brooklyn, St. Louis, and Baltimore two each, Philadelphia one. From *whooping-cough*, New York five, Brooklyn three, St. Louis and District of Columbia two each, Philadelphia, Chicago, Pittsburg, Salem, and Ashland one each. From *cerebro-spinal meningitis*, Chicago three, New York, Lowell, and Fall River two each, Philadelphia, Salem, Somerville, and Dedham one each. From *puerperal fever*, Chicago three, Brooklyn, Boston, and St. Louis two each, Cincinnati, District of Columbia, and Providence one each. From *small-pox*, St. Louis two, Philadelphia and New Orleans one each. From *typhus fever*, Chicago one.

Six cases of small-pox were reported in St. Louis, Nashville one; scarlet fever 55, diphtheria 26, and typhoid fever eight in Boston; scarlet fever 29, and diphtheria nine in Milwaukee.

In the 83 cities and towns of Massachusetts, with an estimated population of 1,218,000 (estimated population of the State 1,922,530), the total death-rate for the week was 18.00 against 21.05 and 18.60 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending December 22d, the death-rate was 21.9. Deaths reported 3624: acute diseases of the respiratory organs (London) 391, scarlet fever 129, measles 126, whooping-cough 77, fever 73, diphtheria 30, diarrhœa 30, small-pox (Birmingham four, London and Sunderland two each) eight. The death-rates ranged from 15.0 in Bolton to 29.0 in Halifax; Bradford 16.6; Nottingham 17.3; Sunderland 21.1; London 21.2; Leeds 21.9; Birmingham 22.9; Sheffield 23.1; Liverpool 24.2; Manchester 26.3; Newcastle-on-Tyne 27.6. In Edinburgh 16.6; Dublin 26; Glasgow 36.1.

For the week ending December 15th, in 170 German cities and towns, with an estimated population of 8,655,232, the death-rate was 19.2. Deaths reported 4052; under five years of age, 1853; consumption 567, lung diseases 492, diphtheria and croup 293, diarrhœal diseases 114, scarlet fever 96, measles and rötheln 94, whooping-cough 61, typhoid fever 46, puerperal fever 18. The death-rates ranged from 13.4 in Würzburg to 39 in Liegnitz; Königsberg 30.8; Breslau 31.8; Munich 29.3; Dresden 26.6; Berlin 22.5; Leipzig 27.2; Hamburg 24.9; Cologne 23.8; Frankfort a. M. 18.9; Strasburg 21.

The meteorological record for the week ending January 5th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

RESOLUTIONS ON THE DEATH OF THE LATE DR. S. P. DRESSER.

At a meeting of the Berkshire District Medical Society, held at Pittsfield, December 26, 1883, the following preamble and resolutions were unanimously passed: —

Whereas, Dr. Simeon P. Dresser, of Hinsdale, has been stricken down in the full meridian of life and in the midst of his usefulness, we his Fellows deplore his sad and sudden death, and our own painful sense of the bereavement we have sustained therefrom.

Resolved, That we recognize an irreparable loss to the Society to which he belonged and to the community in which he so usefully labored.

Resolved, That his social and genial nature endeared him as a companion to every one brought within his influence.

Resolved, That we will cherish his memory as a sound and able physician, and skillful surgeon.

Resolved, That we will transmit to the family of our deceased brother a copy of our proceedings and resolutions, together with our deep condolence upon the calamity which has overtaken them.

A. M. Smith,
F. K. Paddock,
William M. Mercer.

ACTION OF THE PROVIDENCE MEDICAL ASSOCIATION UPON THE DEATH OF DR. T. W. PERRY.

At a regular meeting, held January 7, 1884, the Vice-president, Dr. William J. Burge, occupied the chair, and appointed Drs. J. W. C. Ely, E. T. Caswell, and Charles O'Leary a committee to draft a minute relative to the death of Dr. T. W. Perry, which occurred, suddenly, of angina pectoris, at the office of Dr. Bowditch, Boston, on the 5th instant.

The committee submitted the following, which was unanimously adopted: —

"In the death of Dr. Thomas W. Perry the Society has lost a member of twenty years' standing, who had achieved an honorable position as a practitioner, and by the qualities of his heart, his cheerfulness, and his zeal, secured the affection of his large circle of patients. His professional brethren recognized in him one who was always ready to learn and to appreciate fully the attainments of others. Amid various trials and afflictions he bore himself with fortitude, and was prepared for the final change whenever it might come to him."

It was also voted that the above be entered upon the records of the Association. William R. White, M. D., *Secretary.*

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM DECEMBER 28, 1883, TO JANUARY 11, 1884.

Appel, Daniel M., captain and assistant surgeon, having relinquished the unexpired portion of leave of absence granted by S. O. 68, headquarters Division of the Atlantic, November 16, 1883, and reported for assignment, assigned to duty at Fort Porter, N. Y. Paragraph 2, S. O. 247, Department of the East, December 29, 1883.

Brown, P. R., captain and assistant surgeon. Assigned to duty at Fort Huachuca, A. T. Paragraph 9, S. O. 119, Department of Arizona, December 27, 1883.

Havard, Valery, captain and assistant surgeon. Assigned to duty in charge of office of medical director, Department of Texas, during the temporary absence of that officer. Paragraph 2, S. O. 164, Department of Texas, December 31, 1883.

Egan, P. R., first lieutenant and assistant surgeon. Upon reporting of relief to proceed without delay from Fort Huachuca, A. T., to Fort Apache, A. T., and report to the commanding officer for duty at that post. S. O. 119, Department of Arizona, December 27, 1883.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE TWO WEEKS ENDING JANUARY 12, 1884.

Hudson, A., medical inspector, from duty as assistant to the Bureau of Medicine and Surgery, on the 18th inst., to the U. S. S. Lancaster, as the relief of Medical Inspector N. L. Bates, who is to be detached and ordered home.

Russell, A. C. H., passed assistant surgeon. From the Navy Yard, Washington, to hold himself in readiness for sea service.

McMurtrie, D., surgeon. Ordered to the Naval Rendezvous, Philadelphia, Penn.

Price, A. F., surgeon. Detached from the Receiving Ship St. Louis on the 15th, and ordered to the U. S. S. Ossipee on the 22d.

Russell, A. C. H., passed assistant surgeon. Ordered to the U. S. S. Ossipee on the 22d.

Eckstein, H. C., passed assistant surgeon. Detached from the Naval Hospital, Philadelphia, and ordered to the Receiving Ship St. Louis.

Wells, Howard, passed assistant surgeon. From the Naval Rendezvous, Philadelphia, and ordered to the Naval Hospital, Philadelphia.

Original Articles.

NEPHRECTOMY FOR THE REMOVAL OF CANCEROUS OR SARCOMATOUS TUMORS OF THE KIDNEY.

BY JOHN HOMANS, M. D.,
Surgeon Massachusetts General Hospital.

In the table of cases given below will be found only those where an operation was undertaken to remove a *sarcomatous* or *cancerous* kidney, or where the operation being undertaken on a different diagnosis eventuated in a nephrectomy for sarcoma or carcinoma. I have purposely excluded all cases of removal of the kidney for cystic disease, for floating kidney, for suppuration of the kidney filled with calcareous masses, or for any purpose other than that of removing a kidney affected with one of the two kinds of tumor mentioned above. At my request Dr. Howard Lombard has looked over the literature of the subject, and has found twenty-five cases of the kind mentioned above. If we add to these my own case, to be described later, we have twenty-six cases in the accompanying table.

Dr. Lombard finds upwards of 130 reported cases of nephrectomy, and out of this number the operation has been done twenty-five times (with mine twenty-six times) for malignant disease, namely, for sarcoma twelve times, for carcinoma six times, for encephaloid four times, for adenoma once, and for doubtful tumors three times. In these twenty-six cases there have been eight recoveries, seventeen deaths, and one patient was under treatment at the time the case was reported. The causes of death were as follows: primary hæmorrhage, two; collapse, two; peritonitis, five; septic peritonitis, two; shock, two; pulmonary embolism, septicæmia, return of disease, and cause unknown, one each.

The incision was made in the lumbar region in seven cases, of which four recovered, two died, and one was under treatment when reported. In nineteen cases the incision was ventral, and fifteen died. The operation we have found reported fourteen times in Germany, six times in England, five times in the United States, and once in France.

My own case, in which the fatal result is to be attributed more or less to want of skill, occurred in a man, twenty-nine years old, single, a sailor by occupation. He dated his abdominal trouble from the time he lifted a heavy stone, two years or more before.

History when first seen. He discovered the tumor fifteen months ago, in the left hypochondrium. He has been growing thin, and has not worked any since the pain in his back began, two years ago, at which time he first noticed blood in his urine; this has appeared from time to time irregularly; sometimes his urethra has been plugged with clots so that he has drawn them out in long masses, and once as the plugs of coagulum could not be drawn out he was catheterized. He has more pain when his urine begins to be bloody. The pain in his back is what prevents him from working; when he jumps, or stumbles, or stubs his foot his back aches. He sleeps fairly well; his appetite is variable; his strength is failing. The tumor is a hard, flattened, oval mass, extending from the splenic region to the iliac region on the left side. It is about four and one half by nine inches in its diameters, and feels at first as if it were an hypertrophied spleen. At the same time it projects downwards into the anatomical site of the left kidney as well as upwards under the ribs. It is moved freely during respiration, and falls over towards the right side a little when the patient turns on his right side. It is uncertain whether it is within the peritonæum or whether it has pushed the peritonæum before it. About one third of the tumor lies under the ribs in the left hypochondriac and thoracic region. Dr. E. G. Cutler examined the blood, and found no increase in the number of white corpuscles, and no more albumen in the bloody urine than the blood would account for; no pus and no diminution in the amount of urea; he did find, however, blood casts from the tubules, from the ureter, and, perhaps, from the urethra. I found no stone in the bladder to account for the hæmorrhage.

I reasoned somewhat in this way: If the tumor is an enlarged spleen it causes hæmorrhage by pressure on the renal vessels, or else the renal hæmorrhage is like the nose-bleed that accompanies an enlargement of the spleen. If the hæmorrhage were caused by a calculus in the kidney there would be pus in the urine, and the urine would decompose. The tumor fills the left lumbar region, and *seems* to have grown from the lumbar rather than from the hypochondriac region. I was inclined to think the tumor one of the kidney, and very probably malignant. The man had come from a distance to have the tumor removed, and his decision was unchanged when the nature and possible result of the operation was explained to him. After delaying several weeks that the case might be thoroughly considered, and after consultations with competent advisers, an operation was decided upon, and was done at St. Margaret's Home on November 24, 1883.

Operation one hour's duration; performed antiseptically under a spray of carbolic acid. An incision about five inches long was made through the linea semilunaris. After the peritonæum was opened it was seen that the descending colon had been pushed forward, and that an incision about half an inch long had been made in one wall. A director had been used, and the abdomen had been opened as carefully as usual. Probably it was owing to the thinness and great flattening of the colon squeezed between the tumor and the anterior abdominal wall that the wound was made. This cut was sewn up with a continuous suture of carbolized silk, and the operation was proceeded with. The incision was extended downwards near to the anterior-superior spine of the ilium and upwards through the cartilage of a rib. Another incision, about three and a half inches long, was made backwards at a right angle to the first incision. The tumor could now be seen gliding upwards and downwards beneath the peritonæum as the respiratory movements took place. The posterior wall of the peritonæum was now cut through, and an attempt made to peel out the lower extremity of the tumor, and raise it from its bed. This was accomplished with some slight hæmorrhage from the peritonæum near the hilus of the kidney. The upper end of the tumor was now sought for, and pulled up very much as one would at an autopsy. The strain on the renal vein at this time was very great. When the tumor had been raised up at both ends the fold of peritonæum enveloping it was pushed back more or less, and the ureter and renal vessels were clamped in a large Spencer Wells's clamp. The pedicle was then tied with carbolized silk, and the clamp removed while the ligature was being tightened.

Operator and Original Record.	Sex and Age.	Diagnosis or Aim of Operation.	Evil dates Back.	Date of Operation.	Seat of Incision.	Form of Dressing.	Treatment of Pedicle.	Symptoms after Operation.	Result, Immediate and Eventual.	Hæmorrhage at or after Operation.	Condition of Organ Removed.	Remarks.
1. Walcott (America). Med. and Surg. Reporter, Phil., 1861, vol. vii.	M. 58	Diag., cyst of liver.	Six years.	1861, June 4.	Ventral.	—	—	—	Death fifteen days after, from exhaustion of suppuration.	—	Encephaloid of right kidney. Weight, two and a half pounds.	—
2. Peaslee (New York). Ovarian Tumors.	F. —	Diag., ovarian growth.	—	1868, April.	Median Abdominal.	—	—	Free evacuation of urine.	Death fifty hours after of peritonitis.	—	Solid renal tumor.	—
3. Langenbuch (Germany). Berlin. klin. Wochenschr., No. 24, 1877.	F. 32	Diag., sarcoma of lumbar muscles or of kidney.	Eighteen months.	1875, December 7.	Lumbar.	Antiseptic.	Ligature difficult; slipped off.	None bad. No fever.	Recovery. Left hospital January, 1876.	Slight when ligature slipped.	Doubtful. A hollow organ.	There is some doubt as to nature of diseased mass, specimen having been thrown away by inadvertence of servant.
4. Koehler (Bern). Deutsch. Zeitschr. f. Chir., Bd. ix., 1878.	F. 35	Sarcoma of a freely movable kidney.	Eighteen months.	1876, April 20.	Ventral, high.	Antiseptic failed.	Not reached.	Only thing remarkable was cystitis second day.	Death third day, from peritonitis.	None noted.	Sarcoma. Extensive.	Operation abandoned, the growth spreading too far into transverse mesocolon to be separable. Abdominal incision stitched up.
5. C. Hüter bei Schüller (Greifswald). Deutsch. Zeitschr. f. Chir., Bd. ix., p. 572.	F. 4	Diag splenic or ovarian growth.	One year.	1876, July 4.	Linea alba.	Strictly antiseptic.	Not reached.	—	Death during operation from hæmorrhage from renal vessels.	Furious at.	Right kidney atrophied, with attached parenephritic sarcoma.	Tumor weighed nearly five pounds. Twenty-two cm. by fourteen by 11.6. Commenced at hilus and spread into kidney.
6. Jessop (Leeds). London Lancet, 1877, vol. i.	M. 2½	Renal encephaloid.	One year.	1877, January 7.	Lumbar.	Not antiseptic.	Lig.; whip cord.	None bad. No vomiting. Good flow of urine.	Recovery. Child up and running about soon after.	—	—	Eight months later recurrence was evidently taking place, probably in lumbar glands. Child died a few weeks later at its home. No autopsy.
7. Koehler (Bern). Deutsch. Zeitschr. f. Chir., Bd. ix., 1878.	M 2½	Renal new growth.	2½ years	1877, Sept. 27.	Ventral.	Antiseptic.	Lig.; double catgut.	No uræmia; no vomiting; free flow of urine soon after.	Death third day, of septic peritonitis.	Considerable during. None from pedicle.	Adeno-sarcoma. Three pounds, fifteen by sixteen by ten cm.	—
8. Byford (America). Trans. Amer. Gynæcolog. Society, 1880, p. 71.	F. 39	Encephaloid of right kidney.	Eighteen months.	1878, March 14.	Linea alba, 7 inches.	Strictly Listerian.	Lig. in three parts, with silk cut short.	None of note.	Recovery rapid and complete.	None.	Four and a half pounds. Encephaloid throughout.	Patient last seen in July, 1880, in perfect health.
9. Martin (Berlin). Berlin. Klin. Wochenschr., 1879, No. 22.	F. 53	Sarcoma of kidney.	Two months.	1878, December 9.	Ventral.	Strictly antiseptic.	Ligature; nine silk.	—	Recovery complete. Out of bed eighth day; went home seventeenth.	None.	Malignant new growth. Weight twenty-eight ounces. Microscope showed to be sarcoma.	Operation lasted 45 minutes. Rendered particularly difficult by presence of large, engorged veins running over the tumor.
10. Czerny (Heidelberg). Centralblatt f. Chirurgie, No. 45, 1879.	M. 50	Malignant tumor of kidney.	Two years.	1879, January 19.	Ventral.	—	Not reached.	Death ten hours after, of shock.	Hæmorrhage profuse at operation; from renal artery.	Soft, spongy mass left in situ. Medullary sarcoma.	—	Having broken into soft mass of tumor during operation, profuse bleeding set in from renal artery. Aorta then ligatured.
11. Lorsen (Heidelberg). Deutsch Zeitschr. f. Chir. Bd. xiii., Heft 3, 4, 1880.	F. 37 years. Six mos. advanc. in 9th pregnancy.	Diag., tumor of right ovary. No true urinary symptoms.	One year.	1879, August 11.	Linea alba.	Antiseptic carbolic spray.	Ligature of ureter first; later pedicle, with No. 2 silk, not by transfixion.	Shock from loss of blood and from carbolic intoxication. Abortion twelve hours after operation. Endometritis sixth day.	Recovery perfect. Returned home September 25th. Amount of urine rose to normal in nine days. At first was one half normal quantity.	Very severe at, from pedicle on slipping of ligature when kidney was cut away.	Quite healthy angio-sarcoma, five to six times size of kidney. Grew from surface of latter.	Most remarkable case. The only bad symptoms were clearly due to endometritis and carbolic intoxication. Still reports herself well in June, 1881.

12. Bardenhauer (Cologne). Die Drainirung der Peritoneal-höhle, Stuttgart, 1881, s. 257.	F. 22	Diag., perinephritic abscess, following renal calculus or tumor.	Since June, 1879.	1879, Nov. 23.	Lumbar.	—	Ligature en masse.	Profound collapse. Considerable fever.	Death December 3d, presumably from sepsis, which existed before operation.	Profuse from cavity of abscess.	Spindle-cell sarcoma, size of hen's egg.	—
13. Barker (London). Trans. Medico-Chir. Society, vol. lxiii., 1880.	F. 21	Encephaloid of right kidney.	Eight mos.	1879, Dec. 23.	Linea alba.	Strictly Listerian. Antiseptic.	Transfixed and tied twice, vessels separately after. Silk cut short.	No shock, but vomiting continued to last. Senses clear throughout.	Death forty-five hours later, from pulmonary thrombosis.	None during or after. Operation practically bloodless.	Two thirds of organ converted into a mass of encephaloid. Weight 30½ ounces; 7 by 4½ by 4½ inches.	Whole operation passed off without difficulty.
14. Czerny (Heidelberg). Archiv. f. Clin. Chir., Bd. xxv., Heft 4, s. 858.	M. 23 Phthisis.	Diag., hydronephrosis of left kidney. Tapped in 1880 in front of axillary line.	Probably congenital. Painful. Three years. Had burst three times.	1880, March 9. Lasted three hours.	From old fistula in front of axillary line, parallel to Poupart's ligament. Later prolonged up to twelfth rib.	Lister throughout, with drainage tubes.	Ureter tied; also artery and vein; later, twelve other vessels.	Death half an hour after, from shock, chill, and carbolic intoxication.	—	Hardly any after.	Hydronephrotic, and full of masses of large round-cell sarcoma.	Post mortem revealed glandular infiltration, tubercular deposits in liver, spleen, kidney and lungs. Old pleuritis and pericarditis.
15. Czerny (Heidelberg). Deut. med. Wochenschrift, 1881.	F. 11 mos.	Tumor of left kidney.	Six weeks.	1880, August 2.	Abdominal median.	Antiseptic.	Six silk ligatures.	Considerable vomiting and diarrhœa.	Death three days after, of septic peritonitis.	Slight.	Adenoma larger than the head.	From danger of carbolic poisoning carbol. acid had to be used very sparingly. Child quite weak bef. op.

26. John Homans (Boston, U. S. A.). Boston Med. and Surg. Journal, January 24, 1884.	M. 29	Renal tumor.	Two years.	1883, Nov. 24.	Linea semilunaris.	Antiseptic spray.	Transfixed. Tied with Tait's knot carbonized silk.	Suppression of urine. Patient very quiet and calm, almost dull.	Death fifty-one hours after operation. Acute general peritonitis.	None.	Carcinoma of the left kidney. Three and a half pounds.	At the autopsy there was found acute general peritonitis, infiltration of kidneys. Fatty infiltration of liver, with cloudy swelling, edema, and thrombosis of veins; blood in lungs, and wound of intestine.

The substance of the kidney was then cut through on a level with the pelvis. Warm sponges were put in the place formerly occupied by the tumor, and the rest of the peritoneal cavity was examined for clots. A large India-rubber drainage tube was passed out through the loin, an incision having been made for the purpose. The anterior and lateral incisions were then sewed up after the abdominal cavity had been thoroughly cleaned, and the wounds were dressed antiseptically. An enema of a drachm of laudanum and an ounce of brandy was given, and the patient was removed to his bed with a good strong pulse.

During the next twenty-four hours his temperature was about 100° F. *Only four ounces* of urine were secreted. He had no vomiting until ten A. M. of the day following the operation. During the last twenty-seven hours of his life fifteen drachms of urine were drawn off, so that during the fifty-one hours that he lived after the operation he passed but five ounces seven drachms of urine. He sank away, and died rather suddenly and quietly without having suffered much. He vomited more or less, and was very quiet, in fact rather dull. The urine was dark-colored, thick, and intensely acid. If the suppression of the urine was due to carbolic acid the temperature ought to have been below normal rather than above. It would have been wiser, however, to have used some other reagent or else to have omitted the spray altogether.

The following is Dr. Whitney's account of the autopsy: —

Autopsy twenty-four hours after death.

Rigor mortis present.

Body warm. A fifteen to twenty centimetres long wound in the abdominal wall, to the left of median line, closed by an interrupted suture.

An opening in the left lumbar region, from which a drainage pipe projected.

Head not opened.

Pericardium contained about thirty cubic centimetres of serous fluid.

Right lung bound to chest wall by moderately firm old adhesions. Left lung free. Lungs did not fully collapse upon removal from the chest. Upon section a thin fluid mixed with air issued from the dark-red surface.

Heart normal in size. Muscular substance markedly decomposed.

The coils of the intestine were joined by soft, purulent, flaky masses, and the surface was covered by a thin layer of purulent lymph. A little purulent and bloody fluid was in the pelvis.

Just below the splenic flexure of the colon was an opening into the bowel, which had been drawn together by a continuous suture.

In the place of the left kidney was a ragged opening through the peritonæum, which, as well as the deep muscles, was infiltrated with blood. A number of thrombosed veins were found.

No enlarged glands were noticed in the mesentery or neighborhood.

The right kidney was about normal in size. The superficial veins injected. Upon section it was found to be whitish, opaque, and marked by an occasional yellow line. Microscopic examination showed the presence of fat in many of the tubules.

The liver was opaque. The periphery of the acini yellow, the centres red. Microscope showed moderate fatty infiltration with a granular degeneration of cells.

The other organs presented no unusual appearances.

Diagnosis. Acute general peritonitis. Fatty degeneration of kidney. Fatty infiltration of liver with cloudy swelling. Œdema and hypostatic congestion of lungs. Wound of intestine.

A section through the tumor showed a coarsely reticulated structure of alternating fibrous bands, between which were opaque, yellowish, friable masses.

The microscopic examination showed that these last were composed of large epithelial cells, arranged in columns, and lying in small alveolar spaces. No true kidney tissue was found.

Diagnosis. Cancer of kidney.

CASES OF MELANCHOLIA.[1]

BY GEORGE T. TUTTLE, M. D.

I AT first intended this paper to be a report of a case of melancholia with delusions, false sight, and false hearing that recovered while under the opium treatment, but its scope has been somewhat enlarged, and it is my purpose to briefly report or allude to several cases of melancholia where the medical treatment was opium, or a mixture of cannabis Indica and bromide of potassium or sodium.

It is well known that the presence of false sight and hearing for any length of time in a case of melancholia, indeed in any form of mental disease, warrants an unfavorable prognosis. The case I shall first report was of this character, and the chance of recovery was thought to be small.

E. C. H. was admitted to the McLean Asylum May 7, 1882; a man thirty-eight years of age; married; a merchant. No insanity in the family. He had usually been well except for occasional attacks of facial neuralgia that occurred at irregular intervals, of a few days or weeks, and lasted from half a day to two days. He was always of a nervous temperament, worried over little things. For a while he had been in charge of a branch house in another city, and had worked very hard; it is not possible to give any other as the exciting cause of his illness.

About the first of January (four months before admission) he began to appear nervous and irritable, and was unable to sleep well. He soon showed less capacity for business; then he had the idea that he had lost his place in the firm, and that his wife and children would suffer.

About the first of March he went to his home in an adjoining town, as he was totally unfit for work. He had grown worse. From worrying about business affairs he had taken another step and thought he had committed the unpardonable sin. Two weeks before admission he bought laudanum with the intention of suicide. On the morning of admission he was found with a rope and stone attached going towards a cistern, evidently intending to drown himself. Because of these attempts at suicide he was brought to the asylum. He was by no means demented, though the physician's certificate, under which he was committed, read, "A species of dementia, fatuity."

A physical examination revealed nothing abnormal. He showed much agitation and loss of self control, walking the floor, wringing his hands, and muttering. He answered questions readily, but repeated his answers several times as though in great distress and scarcely realizing what he was doing. He was given cannabis Indica, in the form of the tincture, one grain, and potassium bromide twenty grains, three times a day.

This agitation continued for several days, attended with loss of sleep, but he soon appeared in a way able to listen to reason, and it was almost possible to convince him that his ideas were wrong. On the 15th (eight days after admission) his wife, whom he left at home sick, and of whose recovery he had no hope, made him a call. This was of great benefit.

Under the cannabis and bromide, with plenty of food, rest, fresh air, and what diversion could be afforded, he improved rapidly, and began to read and take an interest in affairs. By the 23d of June he appeared so well that he was on that date allowed to spend the day at home, with a favorable result. The cannabis Indica and bromide had been gradually reduced till by this time he was taking only one fourth grain of the former and five grains of the latter.

At a subsequent visit, however, about the 6th or 7th of July, he became disturbed, and was not so well after returning to the asylum. Three days later he became much agitated, trembling because of fear; was afraid of those about him. The cannabis and bromide was resumed in full doses (one grain cannabis, twenty grains bromide).

At this time he revealed the delusion that there were various articles in the papers referring to him, and that people talked about him. This did not appear to have been false hearing. He had simply overheard the conversation of his associates and made what they said apply to himself, just as he did what he read in the papers.

About this time he did have unmistakable false hearing and illusions of sight.

He heard his father-in-law talk to him in the night, and the capitals of several Corinthian pillars which, on another building, he could see from his window, appeared to him to be grinning faces. When fully under the influence of the cannabis and bromide he became quite calm, though his depression was considerable and attended with the usual delusions of great wickedness and terrible punishment. He often said that while he was perfectly certain this was so, it was a wonder to him that he could go in the garden, smoke his cigar, and talk composedly with people. During the summer many things foretold his approaching doom: the reflection of the setting sun from the windows of the city was to him ominous; the locomotive bells tolled instead of ringing as they used to do; even the flowers in the garden reviled him.

In the fall he grew worse. He frequently heard the voice of his wife, which appeared to come from the sky, and often saw in his path a skull and crossbones which foretold his fate. He used to try to point this out to others, but no stretch of the imagination could detect any resemblance, for he usually saw some figure on the carpet or spot on the gravel walk.

As he did not appear to be gaining, and the cannabis and bromide merely kept him from a state of extreme agitation, and more especially as he began to complain that his gait was unsteady and that he had some difficulty in directing the movements of his hands, it was gradually changed during the latter part of November to deodorized tincture of opium, of which he

[1] Read before the Boston Society for Medical Observation, December 3, 1883.

took twenty to twenty-five minims three times a day during December and January.

There was, however, no improvement in his mental condition. False sight and hearing continued; shadows on the curtains were to him living faces; the paper in his room had been selected with special reference to him, and the design represented many knives, which were a constant threat of death; and he at last had the idea that he was to be taken to Mount Auburn and buried alive or left in a tomb to starve.

He grew worse also in his physical condition; his appetite failed, and there was marked loss of flesh and strength, but it was decided notwithstanding to push the treatment more vigorously, and the 1st of February the deodorized tincture was changed to sulphate of morphia, and the dose rapidly increased from five eighths to three fourths of a grain, which he took from February to September, as it was enough to completely control his restlessness.

Under the larger doses of morphia his appetite improved and he slept better, without the moderate dose of chloral and bromide which he had sometimes taken, and the attacks of facial neuralgia became much less frequent.

He gradually dropped his ideas of wickedness and torture; there was no evidence of false hearing, and by the early summer he had begun to read the papers and books.

June 23d he went home for the day. After making several visits of a day, he stayed over one night; then a longer time. During these visits he appeared very happy, playing with his children, meeting his friends in a natural way, and took sufficient interest in his business and other affairs to occupy his attention. On the 19th of September he went away on a visit, not to return unless necessary. He had by this time given up all idea of having done wrong, and was only anxious to get back to his business and family.

He has since been seen and heard from several times, and the reports have always been favorable. He was discharged recovered after twenty months' illness.

Another case closely resembling this in its essential features was that of a woman (L. H.) forty-nine years of age, who was admitted July 22, 1882. Father and mother both committed suicide. She was one of nine children, none of whom except herself had been insane. Had had two previous attacks of melancholia, the first in 1853, the second in 1869. Present attack of six weeks' duration caused by anxiety and loss of sleep incident to the care of a sick relative.

The growth of her delusions was in this wise: Exhausted by watching, and over anxious, she at first feared she had not done her duty; then thought she *had* not; then that she was a sinner; then that the deaths in the family were a judgment upon her; and finally, that she was a murderess. She was suicidal.

In a general way the treatment till December was occasional doses of sedative medicines at night, and special attention to diet and the general conditions of health. But she grew worse; was apparently in the depths of despair; constantly moving about, talking, and showing great restlessness and agitation, which at times amounted almost to incoherence.

In a month from the time of admission she had the most marked false hearing. People made various accusations against her; she could hear vulgar talk and laughter and remarks against her character. In another month (by the middle of September) she was still worse; thought she was an animal, and that repairs in process on an adjoining building were to construct her a pen. Appetite was pretty good, but she thought she ought not to eat because of her crimes. In consequence of this she would beg, cry, and struggle in a distressing and noisy way when the nurses attempted to give her food.

December 1st she was given deodorized tincture of opium, ten minims three times a day regularly, and by the 14th it had been increased to twenty minims. At this time she was in a more comfortable state of mind, sleeping well without sedatives at night, eating without trouble, and could occupy herself a part of the time with needle-work or some household duty.

During the latter part of January she was not as well for a time, but after an increase of the opium, February 1st, to thirty minims, she regained her balance, and continued to improve till the latter part of March, when, for a week or two, she was much more anxious and restless; but this gradually passed off, and by the 28th of June she was allowed to go home on trial, after a hospital residence of eleven months, and seven months after the beginning of the opium treatment. She now seems to be well.

Another case of the apparently successful use of opium was that of a man (H. W.) sixty-one years of age, a merchant, who was admitted January 15, 1883. First attack of a few weeks' duration. Exciting cause, failure in business. His mother and sister had been insane. He was of a nervous temperament, but usually well.

After his failure he appeared much depressed in mind, and soon restless, going without apparent object from place to place, showing a want of self-control by his conversation as well as actions, and, as he was found to be carrying a revolver and a razor, his friends thought it safer for him to come to the asylum, though he had made no attempt at suicide.

For a few days after entrance his restlessness and agitation were considerable. He would walk the floor with his hands to his head, saying, "Oh, dear! what have I done? what have I done?" While taking deodorized tincture of opium in the moderate dose of twenty minims three times a day, he regained his self-control, though his depression was not then the less. With careful attention to his general health he rapidly improved, and March 31st he went home in a very comfortable condition, after a hospital residence of two and one half months. As subsequent reports were favorable he was discharged, recovered.

The opium treatment has been given in six other cases of melancholia, to which I will briefly allude.

A man (D. W. F.), fifty-three years of age, had been depressed in mind for six months, and for two months had had delusions about his business affairs; that his family was coming to want, and, as they would freeze or starve, had better die at once. Was suicidal; no false sight or hearing.

For nine months he took ten to twenty minims of the deodorized tincture three times a day. Under the latter dose he became calmer, slept better, ate better, and gained in flesh and strength. He is now at home and well enough to be making plans for engaging in business.

A man (R. S. M.), sixty years of age, had been suffering from melancholia for six months previous to admission. His intelligence was good, but he lacked will-power, and after he finally came to a decision on

any question worried for fear he had made a mistake. He could not sit and read or talk, but walked the floor till tired enough to lie down, and when partially rested began his walk again. Slept poorly. He took twenty minims deodorized tincture three times a day for five months, and was then nearly as restless as at the beginning of the treatment, and his mental condition was not much improved. I must in fairness say, however, that he had gained a few pounds in weight, and that the opium at least did him no harm, and he held the slight improvement after stopping the treatment.

Another man (J. B. J.), fifty-two years of age, with delusions, false sight and hearing, a case of nine months' duration, in which no sort of treatment could have been applied with much hope of success, was given in a mild way meconate of morphia (one eighth to one fourth of a grain three times a day), for two months, during which time he steadily grew worse. The man is now no better, after an illness of three years.

A woman (T.), fifty-six years of age, second attack, of seven weeks' duration, was in great distress of mind, fearful of coming destruction, in constant motion, moaning and crying, at times beating her head against the wall and trying to choke herself with her hands. No evidence of false sight or hearing. She was given one fourth of a grain of meconate of morphia at bedtime for a month, and one sixth to one fourth of a grain three times a day for six weeks, but did not improve. A criticism applicable to this and the preceding case is that the dose was not large enough nor long enough continued.

Two women are now under treatment. Both are cases that one might expect to benefit with opium, as they show great agitation and distress of mind, walking the floor, crying and wringing their hands; insomnia and anorexia. One is now taking one grain of morphia sulphate three times a day, and the treatment has been pursued between two and three months, the dose having been gradually increased to the present amount. There is as yet little improvement.

The other case is complicated with false hearing and possibly sight. The treatment has been pursued nearly two months. She is now taking one and one quarter grains of morphia sulphate three times a day, and is no better.

Not considering the two cases now under treatment, of the seven cases reported three recovered; one was much improved; one was improved in a slight degree, and two grew worse. (In these two cases the treatment was not satisfactory, the dose was too small.)

It will be remembered that in the case first mentioned the treatment at the beginning was a mixture of cannabis Indica and bromide of potash, in the proportion of one grain of the cannabis to twenty grains of the bromide, as recommended by Dr. Clouston in his essay on Opium, Potassium Bromide, and Cannabis Indica.[1] It has been quite largely used at McLean Asylum, more particularly and with greater success in cases of maniacal excitement; but it has also been tried in a number of cases of melancholia, in several with benefit, and in one with marked success. This was the case of a man (W. F.), thirty-nine years of age, an architect, who was admitted January 28, 1882. A former attack of melancholia in 1864 lasted one year. Present attack, of six months' duration, was apparently caused by the death of his wife. He had the usual ideas of a man suffering from melancholia, and was suicidal. He showed considerable restlessness and agitation, not extreme, to be sure, but he could not confine his attention to anything, and walked about aimlessly.

He was given three fourths of a grain of cannabis and fifteen grains of bromide three times a day (A. M., P. M., and before sleeping), which was increased July 4th to one grain cannabis and twenty grains bromide. He became more composed, and could take his part in a conversation to the amusement and instruction of others, for he was a very well-informed man, but would not admit that his depression of mind was less. By July 21st he was busy with his pencil and brush. With the usual care in regulating his daily life, he continued to do well, gaining in flesh and spirits, and the medicine was gradually reduced during September and October till he took one fourth grain cannabis and five grains bromide. He gradually grew worse; his old restlessness and depression returned in some degree; he looked haggard and was evidently losing flesh. November 4th the cannabis was increased to three fourths of a grain and the bromide to fifteen grains three times a day. He soon appeared better, and on the 18th it was reduced to one half grain cannabis and ten grains bromide.

From this time his progress was steady, and he left the asylum January 27, 1883, after a hospital residence of seven months. He was discharged recovered.

Another case was a woman (A. M.), fifty-five years of age. Of four sisters who had been insane one was at the time of admission an inmate of the McLean Asylum; one sister and a brother had committed suicide.

She was inclined to talk much of religion, her wickedness, and the certainty of a terrible punishment. She had delusions, such as that the nerves of her head were dead, broken, and dried up; that her feet and bowels were burning; that she was dying, and others of a like distressing nature. She was determined to commit suicide, and while undressing would often secrete a stocking, a garter, or a towel in the bed, and would shortly be found with it about her neck. Was often fed with the tube. She would be fed for several days or weeks, and then would eat for awhile, and again require feeding. She was very restless and constantly asking questions, frequently repeating the same one, more, apparently, from distress of mind than because of lack of comprehension. Her favorite remark was, "I've done wrong." It appeared to be a hopeless case so far as recovery was concerned, but for her comfort, November 1, 1880, the treatment by cannabis Indica and bromide of potassium was begun, and for four and a half months she took from one to one and a half grains of cannabis and twenty to thirty grains of bromide twice daily, as it appeared in a measure to quiet her.

During the month of December it was for a time omitted. She became more excited and deluded. Perhaps it could not fairly be claimed that her appetite improved under this treatment, but it is a fact that while taking the cannabis and bromide she was not once fed with the tube. She became so much more quiet that she was moved to a better ward. She was still much depressed, and both during this time and on many occasions afterwards attempted suicide. So far as recovery was concerned the use of cannabis and bromide was a failure. She was afterwards given opium in a mild way, the dose was too small to do any good, and she was finally transferred to a State Asylum, not improved.

[1] Brit. and For. Medico-Chir. Rev., Oct., 1870, and Jan., 1871.

Not to weary your patience, I will simply say that of seven other cases treated with cannabis and bromide, one woman in a state of great agitation, constant distress of mind, and extreme suicidal impulse, took from three fourths grain to one grain cannabis and fifteen to twenty grains bromide three times a day for three months with marked benefit. It was then thought best, from her appearance, to omit it for a while, and opium in moderate doses was substituted. This did not succeed. There was loss of appetite, in fact pretty constant nausea, with, of course, loss of flesh, and a change for the worse in mental condition. Cannabis and bromide were afterward resumed with the former good effect, and are still taken.

Another case, still an inmate of the asylum, thought she had committed the unpardonable sin; was fearful of future punishment, greatly agitated, and made foolish attempts at suicide. For four months she took one and one half grains cannabis and thirty grains bromide three times a day, and later one and one fourth grains cannabis and twenty-five grains bromide three times a day for two months, apparently with great benefit. Of two other women, one was discharged recovered, but not while taking the cannabis and bromide, nor because of it; and the other is not improved after having taken for two months one to one and one fourth grains cannabis and twenty to twenty-five grains bromide. One man left the asylum at the end of a month not improved, but this was not a fair trial either in time or dose. In the case of another man it was omitted after four months' trial, and opium substituted, with good results. A third man took it with doubtful benefit for four months.

Not considering the case still under treatment, of the above eight cases one recovered; the cannabis and bromide was of marked benefit in two cases; of doubtful benefit in two; and of no advantage in three (one not having been a fair trial).

The action of this combination seemed to have been mainly sedative, and the effect was to quiet restlessness and give general treatment a fair chance; indeed, if the patient merely becomes calm it is in itself a long step towards recovery. It is perhaps worthy of remark that though the cannabis and bromide were continued in many cases for long periods of time no depressing effects were observable. An increased appetite was noticed in some of the cases, while in others it would be difficult to say the appetite failed, for it could not well be less.

The indications for reducing the dose are symptoms rather of bromism. This occurred in several cases. A woman after taking one and one fourth grains cannabis and twenty-five grains bromide three times a day for six weeks became partially helpless, and had paralysis of the soft palate. From this she recovered in a week or ten days after stopping the medicine. This was the most marked instance, and, except for some slighter occurrences such as this, no bad effect was noticed. After the dose is reduced or omitted it takes several days to get over the effect, as might be expected, and it is as well a matter of a few days to get under its influence.

An objection to the tincture is that it is a bad looking and bad tasting dose, and I prefer a pill of the extract, which has been used to some extent. A solution of bromide containing considerable glycerine has been used, as this will for a day or two prevent a precipitation of the cannabis, which will occur if the simple aqueous solution and tincture are given in one dose.

From a comparison of results in the two series of cases the balance is much in favor of opium, still the cannabis and bromide will do good in some cases, and may sometimes be used when opium cannot. It should therefore not be discarded as a form of medical treatment in melancholia.

Dr. Clouston's conclusion was that "fewer cases of simple melancholia were benefited by the bromide alone or along with Indian hemp than any other form of insanity. Some were made worse by them, but in one case of this disease, when there was great excitement and hallucination of hearing and suspected organic disease of the brain, the combination gave immediate and complete relief of all the symptoms for four months." This conclusion appears to have been based on the observation of five cases.

Opium *may* have some other action, but its main effect appeared to be sedative.

If there were no diminution in the restlessness and agitation of the patient I should doubt any great advantage from its use, and this leads me to say that while it is not possible to predict that a given case will be benefited, in a general way it may be said that the most favorable results are obtained in cases of restless melancholia. In some there is apparent intolerance of the drug; the appetite fails, the patient loses ground, and the treatment must be abandoned. It should, however, be borne in mind that a loss in appetite is not always an indication for stopping its use. The modern idea of the opium treatment of melancholia is somewhat like that in regard to its use in peritonitis as compared with the older method. In treating a given case the dose should be increased till the patient becomes calm, or dangerous symptoms appear. The agitation of a case of melancholia is an entirely different affair from the excitement of mania, in which the use of opium is not advised, and there is, so far as I can see, no danger, with careful watching, in gradually increasing the dose to almost any limit.

Many of the cases reported were severe, and the chances of recovery small; in such more vigorous treatment is warranted than in the ordinary cases of simple melancholia that do well with attention to the general conditions of health and little or no medication. I have seen a modification of the "rest treatment" used with success in several cases of this character. In conclusion, I would remark that it is often extremely difficult to say whether or not a given remedy has been beneficial, and much more so to ascribe to it a cure.

RECENT PROGRESS IN FORENSIC MEDICINE.

BY F. W. DRAPER, M. D.

CREMATION AND CRIME.

BROUARDEL, professor of legal medicine in the Medical Faculty of Paris, in a report made to the Council of Public Health, and adopted by that body in August last, makes the following among other observations concerning the relation of crime to the practice of cremation in times of epidemic invasion.[1] He declares his belief that societies and individuals who seek to promote this method of disposing of dead bodies

[1] Annales d'Hygiène publique et de Médecine légale, October, 1883, page 315.

have not appreciated fully the medico-legal difficulties in their way. Cases of acute poisoning, he says, are of two kinds. One class includes the accidental cases in which it matters little whether the body is buried or burned. Illustrations of the other class present themselves under totally different conditions. One must be living in intimacy with a person to be able without ready detection to mix poison with his food. After the poison has been swallowed the one who has given it is often the nurse of his victim, sometimes the only witness of his sufferings. Frequently many days elapse after the death before rumor calls attention to the case as one of suspicion, and days, weeks, sometimes months and years intervene before the inquest is held. If cremation has effected the destruction of the body of the victim no trace remains permitting the authorities to confirm the guilt of one suspected, or, what is of equal consequence, to demonstrate the innocence of one falsely accused.

If, as those who favor cremation propose, an autopsy is invariably made before the destruction of the body is permitted, a great difficulty will still be encountered. The chemical detection of poisons often requires a month or two months of analysis. How shall we harmonize these complicated and laborious researches with frequent cremation? Then, too, if the expert finds in the dead body an alkaloid or a mineral poison, such as arsenic or mercury, inquiry must be made of the family to ascertain if the deceased person in the last months of his life had not taken as medicine one or another of these poisons.

It does not appear that hygiene finds any advantages from the cremation of dead bodies in times of epidemic invasion. The speedy equipment of proper apparatus for the combustion of several hundred bodies daily is almost an insurmountable difficulty when it is recalled that the best appliances now known cannot reduce an adult body to ashes in less than four hours. On the other hand it is not demonstrated that a cadaver dead from cholera, for example, can become an agent for the spread of the disease. Whether such a body be destroyed by fire or slowly by decomposition in the earth the result appears to be the same. It is impossible to invoke any danger that comes from the burial of cholera victims as a reason for the necessity of adopting the cremation of their bodies.

All writers on toxicology point out the similarity in the symptoms of cholera and of certain forms of poisoning. For example we may recall two of the agents most frequently employed with criminal intent, arsenic and corrosive sublimate, not to mention any of the alkaloids occasionally used in like manner. Dr. Laveran says: "In certain forms of poisoning and at the beginning of epidemics one cannot exercise too much caution in diagnosis." In the East Indies, according to Morehead, criminal poisoning is frequent during epidemics of cholera.

Brouardel sums up his objections to cremation as follows:—

The handling of the bodies subjected to cremation is such as to expose those engaged in the work to greater danger of infection than would be the case in burial.

The interests of justice and those, equally great, of persons unjustly accused of having committed crime, would be seriously compromised by the adoption of cremation.

If cremation is permitted only after an autopsy and an analysis of the viscera it would be necessary before adopting such a scheme to establish a great number of autopsy rooms, and to educate a numerous corps of experts. It is only when these various questions have been seriously considered and properly solved that cremation could be permitted without detriment.

ON DEATH BY COLD.

Dieberg[1] has formulated some valuable conclusions on this subject as the result of his observations on the bodies of thirty-one persons who died by exposure to cold. He found in all these cases that the heart in all its cavities was distended with blood of a fluid consistency and deep color, with an occasional soft clot. He determined the relative fullness of the heart by weight, and shows that although many of the victims of frost may be supposed to have been intoxicated when they became chilled alcohol was not the cause of the death, because in cases of fatal alcoholism alone, without the intervention of cold, he found the weight of the blood contained in the heart to be nearly four times less than in the others.

In explanation of the cause or manner of death in these instances the author states that under the effect of cold the tissues and the vessels undergo a contraction which is in proportion to the temperature depression; that the more superficial and thus the more exposed the vessels are the greater also will be their contraction; that according as the exposure to the cold is prolonged the contraction will progress from the periphery to the centre; that the heart will be able to send only a limited amount of blood forward into the vessels, the latter being unable to receive the normal supply; that the lungs continuing their functions still further supplies of blood are forced in upon the heart, and finally the arrest of that organ is effected, and death by syncope results.

This theory is in accord with facts observed by persons who have survived exposure to a very low temperature. In the report of his voyage to the North Pole Wrangel relates that when the thermometer on one day registered —53° C. every one suffered from headache, tinnitus aurium, subjective optic symptoms, and especially an extremely violent sense of weight and discomfort, indications apparently of circulatory disturbances.

Dieberg believes that death by cold is really due to syncope rather than, as Lesser and Hofmann have held, to asphyxia. In asphyxia one finds at the autopsy dark fluid blood, engorgement of the large veins and the right side of the heart, hyperæmia of the lungs and other organs, punctate hæmorrhages in the serous and mucous membranes. But in death by cold the blood is not always or wholly fluid; it contains clots, especially in the heart. Moreover, its color, instead of being very dark as in asphyxia, is of a brighter hue. Distention of the large veins is not observed, and in the heart the blood is equally distributed in the cavities, and is not found in relatively increased amount in the right side.

The author summarizes his conclusions thus: If, he writes, on making an autopsy upon a frozen cadaver one finds no appreciable lesions to account for the death, but discovers the heart engorged with blood in all its parts, he may declare that the individual was exposed to cold while still living, and that the cold was the cause of the death. If, on the other hand, the

[1] Vierteljahrsch. f. gerichtl. Med. u. offentl. San., xxxviii., page 1.

heart is empty of blood the examiner may conclude that the person was already dead when exposed to the cold, and that another cause of death must be sought for.

PUNCTURED WOUNDS.

Professor Hofmann, of Vienna, states in a recent article[1] that many errors have grown out of the notion which is widely entertained, by physicians as well as by the laity, that one can readily recognize, from the shape of a punctured wound, the kind of weapon which produced it. There is only one class of pointed instruments, those namely with a double edge, which makes wounds whose outlines exactly reproduce those of the weapon. The shape of such wounds is like that of a cross section of the blade, two arcs of a circle meeting at an acute angle. But double-edged blades are not the only ones which produce wounds of this shape; they could be made also by thrusts with a knife having a single cutting edge, or with an instrument conical in shape or many sided. Dupuytren and Malgaigne long ago established the fact that conical weapons make punctured wounds which are not round but linear, and they added the observation that the direction of these wounds was different according to the various parts of the body. In 1861, Langer elaborated these views and showed that the skin has a special "cleavage" for each region. In making deep punctures in various parts of the cadaver, he was able to mark out zones or areas more or less extensive wherein identity of appearances, due to the anatomical structure of the skin, was manifested.

With regard to ordinary knives, it is generally thought that they make wounds whose shape is that of a cone with the base larger or smaller according to the thickness of the blade. Observation shows that this is not true, but that oftener the wound terminates in two tapering ends just as if it had been made by a double-edged weapon.

Wounds made with blades with several faces usually have a stellate form, and the number of rays corresponds with the angles upon the weapon. When the little triangular flaps of skin outlined by the faces of the weapon have been forcibly driven inwards by the thrust, we may have a wound whose shape reproduces that of the blade.

With weapons which have a great number of sides and angles, the angles necessarily becoming more obtuse according to their number, we may have linear wounds like those made with conical blades; but there may often be seen little secondary rents, corresponding to the angles of the weapon, branching from the primary opening.

The foregoing rules are subject to some exceptions. Thus, when a conical weapon wounds a part where different systems of cleavage in the skin converge, the resulting lesion may be triangular. Wounds made with a knife may likewise show secondary cuts when the weapon is turned in withdrawing it. When the knife has penetrated a fold in the skin, the part, if put upon the stretch, will show an opening of zigzag shape.

The dimensions of punctured wounds may supply some indications for identifying the weapon used. But here again experience often contradicts theory. Thus with a conical weapon the wound generally has a length greater than the diameter of the weapon at the point where it was arrested. This is explained by the elasticity of the skin; but as this quality is limited, it may show itself, under the action of a thick conical instrument, in secondary rents, and then the principal wound is shorter than the diameter of the weapon. When one thrusts a very sharp knife into a cadaver, if care be used in entering and withdrawing the blade, a wound results whose length is equal to the width of the instrument at the point where it was arrested in the skin. But almost always the length of the wound exceeds the width of the blade because the cut is enlarged by the lateral movements made involuntarily in the thrust or the withdrawal, so that a very narrow blade may make large wounds and when these are superficial one might readily classify them as incised. It is plain from this that the manner of holding the knife with reference to the cutting edge has great influence on the resulting lesion.

Sometimes, on the other hand, the wound is smaller than the weapon which produced it. This is due to the retraction of the skin, which spreads the edges of the cut and thus approximates its extremities a little. This retraction is more or less marked according to the looseness of the skin's attachment to the subjacent tissues; and it is further modified by the direction in which the thrust was received, whether in a perpendicular or a parallel direction with reference to the line of cleavage in the dermal layers; it is thus that on the extremities wounds perpendicular to the long axis of the limb always gape more than others and hence appear shorter. This affords a practical hint; in taking the dimensions of such wounds it is well to bring the edges of the cut together into a rectilinear shape and then to measure the length only.

Knives whose cutting edge is dull may make punctured wounds much smaller than their own diameter. The same thing results with a cutting instrument sharp at the point and blunt in the rest of its length; in such a case, once the point has penetrated, the thicker part of the instrument simply stretches the skin, which by virtue of its elasticity returns to its previous condition, as far as may be, as soon as the weapon is withdrawn. When a blade of this kind is slowly pushed through the skin, a funnel-shaped depression is seen around the instrument at the point where it penetrates; upon reversing the direction in process of withdrawal, the skin forms a cone around the blade. A bayonet in this way makes a wound which may be a centimetre shorter than the blade's diameter.

If the weapon is very dull, it acts like a wedge and makes a wound whose direction is wholly subordinate to the anatomical structure of the skin; if, for example, one thrusts a dull bayonet into a limb perpendicularly to its axis, the resulting wound has a direction parallel with that axis. In these cases the wound is generally smaller than the weapon, always depending in this regard on the elasticity of the skin. But the aspect of the wound, if it shows secondary rents at its edges, proves that the skin has been stretched, and it thus furnishes important evidence of the nature of the weapon. In making on the same region of the body several punctures with a blunt bayonet, each time in a different direction, one sees that all these wounds are parallel, one with the others, and with the predominant direction of the fibres in the skin; but the direction of the little secondary rents at the edges of the puncture indicates that in which the weapon entered.

MEDICAL EXPERT TESTIMONY.

It is to be regretted that in this important department of forensic medicine there is so little progress to report. The medical expert continues in his equivocal and unsatisfactory relations to the courts, and his testimony is of the familiar pattern in its character, methods, and results. In this State a spasmodic effort was made in the last Legislature to correct the admitted evils and abuses of the prevailing practice. A hearing was had before the Judiciary Committee, and the usual arguments in favor of reform were presented by doctors and lawyers deeply interested in the subject. A bill designed to meet the requirements of the case was formulated by the committee, but the measure perished speedily and ignominiously upon its presentation for legislative action, the opponents of the contemplated change being wholly drawn from the profession whose members are always ready to disparage expert testimony, but are equally ready to purchase some of it when it will serve their needs in the presence of a jury.

The Medico-Legal Society of New York has lately taken its turn in discussing the subject, and has devoted much energy in diagnosticating the disorder which afflicts expert testimony and in suggesting a line of treatment. The discussion was introduced to the attention of the Society by Dr. O. W. Wight, of Detroit, who besides being a physician is also a practicing attorney. In a valuable paper[1] he answers the question, "What is expert testimony and who are experts?" Expert testimony, he writes, just so far forth as it contains the special knowledge of the witness and is pertinent to the issue is relevant, material, and may be essential to the ends of justice; but just so far as it is opinion, personal view or theory, it is irrelevant, immaterial, and may be mischievous. Opinionated expert testimony is repugnant to justice, contrary to law, and alike intolerable to exact science and true art. The presence on the witness stand of one who thinks he knows but who don't know is a judicial misdemeanor; when, therefore, a judge admits a quack expert to testify in his court, for his own enlightenment and that of his jury, he makes himself responsible for the public scandal. Judges forget that in animadverting upon the character of expert witnesses admitted to testify in their courts they are criticising their own negligence. The habit of allowing parties in litigation to select experts beforehand for their ascertained favorable opinions, and to use them as partisan witnesses, is a desecration of the temple of justice.

The author draws a faithful sketch of the partisan expert as he appears in court, under the hands of an "all-sufficient, self-sufficient, in-sufficient" member of the bar, crammed for the occasion; the picture is realistic but unpleasant. Yet Dr. Wight is "hopeful for the future." The expert, he thinks, should be called in by the court, be under the court's considerate protection, and be compensated adequately by the public as other officers of the court are compensated. In no case should the interested parties to a suit be allowed to employ experts; and in turn experts should be prohibited under severe penalties from receiving any fees from litigants. It would be well if medical societies, organized on a sound basis, should designate those who are especially learned and skilled in particular departments of medicine and surgery as proper experts in those departments, and from time to time should furnish a list of such to the courts in their locality. Laws needed to carry out a plan of this kind ought to be speedily enacted.

In a paper reviewing the foregoing article,[2] Judge Delano C. Calvin, of New York, takes exception to Dr. Wight's definition of an expert, and declares that something more is required of the witness than the simple statement of scientific facts, and that the rule regarding the admissibility of opinions should not be modified. He approves, however, of Dr. Wight's plan of selecting experts, as designed to secure competent men, free from temptation to partisanship and prejudice. To the objection that such a scheme would invade the rightful prerogatives of litigants, Judge Calvin replies that all parties would stand alike, and that expert testimony has for its essential purpose the information and education of the court and jury in matters material to the right administration of justice.

The Medico-Legal Society before which these papers were read referred the subject to a committee composed of physicians and barristers; and the report of this committee, while agreeing in general with the views submitted by Dr. Wight, recommends a somewhat novel remedy for the evil. It suggests that "a body of medical experts be chosen by the judges of the Court of Appeals; that these experts be selected from a list of surgeons and physicians, to be recommended by the medical profession in some manner to be determined hereafter; that each physician or surgeon so recommended must have had at least ten years' practice as such, exclusive of hospital service, and that he must have spent at least five years in the active practice and discharge of duties pertaining to the specialty in which he is presented as having expert knowledge; that to these medical experts so chosen be referred all questions of medical jurisprudence arising in the courts; that counsel have a right to submit in writing to these experts any questions pertaining to the matters before them; that these experts report thereon to the court, and give in writing both their answers to and the questions submitted; that a compensation by salary or fee be fixed by the law for their services; that in either case the compensation should be liberal, and such as would amply repay any physician or surgeon for any loss of practice he might sustain or for the time spent in such service; that, as far as practicable, the above body of experts embrace and relate to every branch of medical jurisprudence."

Such are the latest views concerning expert testimony, and its deplorable need of reformatory treatment. Meanwhile, the established rules of law do not help the situation. What these rules are at the present time may be gathered from an instructive book just published, whose author has compiled from all sources the authoritative decisions of the courts of this country concerning expert and opinion evidence.[3] Some of these rules of law, so far as they apply to medical experts, are as follows:—

"The law does not recognize to the exclusion of others any particular school of medicine, or class of practitioners.

"To give an opinion on medical questions, one may be qualified by study without practice or by practice without study. Nor is it absolutely necessary that he should be a physician or have studied for one.

[2] The Medico-Legal Journal, September, 1883, page 200.

[3] The Law of Expert and Opinion Evidence reduced to Rules. By John D. Lawson. St. Louis, 1883.

"The opinion of a medical man is competent as to matters which he has not made a specialty in his study or practice.

"A medical man is not disqualified to give an opinion because he is not a graduate of a college and does not possess a license to practice; or is not at the time in practice; or because a case exactly like the one in question has never been seen or read of by him before.

"A medical man is an expert on the value of medical services, but not as to the measure of damages.

"The jury are not bound by the opinions of medical experts.

"Books of science and art are not admissible in evidence to prove the opinions contained therein; but books of exact science are admissible. An expert may testify to an opinion of his own derived from books; and when a witness has referred to a book as an authority for an opinion, the book is admissible to test his knowledge or to contradict him.

"A witness testifying to matters of opinion may be impeached by proof that upon a former occasion he had expressed a different opinion.

"The qualifications of persons offering themselves as experts may be tested by the opinions of others in the same calling.

"The qualification of a witness to testify as an expert is a question for the trial court, whose decision is not generally reviewable on appeal.

"The opinion of a witness as to his own qualifications is irrelevant.

"One not an expert may give an opinion, founded upon observation, that a certain person is sane or insane."

Such are some of the dogmas which are based on decisions of the highest courts in the various States of this country. Illustrative cases fully adjudicated, of which a great number are cited by Mr. Lawson, appear on every page of his book, and relieve it of the dryness which is said to characterize the literature of the law. The following quotation from a decision by Judge Temple, of the Supreme Court of California, will be an appropriate conclusion to this section of the Report: "Expert witnesses ought to be selected by the court, and should be impartial as well as learned and skillful. A contrary practice, however, is now, probably, too well established to allow the more salutary rule to be enforced; but it must be painfully evident to every practitioner that these witnesses are generally but adroit advocates of the theory upon which the party calling them relies, rather than impartial experts upon whose superior judgment and learning the jury can safely rely. Even men of the highest character and integrity are apt to be prejudiced in favor of the party by whom they are employed; and, as a matter of course, no expert is called until the party calling him is assured that his opinion will be favorable. Such evidence should be received with great caution by the jury, and never allowed, except upon subjects which require unusual scientific attainments or peculiar skill." [1]

— The two latest baronetcies conferred on medical men in England were bestowed on Sir Joseph Lister and Sir William Bowman. The latter is an honorary member of the Massachusetts Medical Society, having been made so in 1881.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES M. WILLIAMS, M. D., SECRETARY.

DECEMBER 3, 1883.

DR. GEORGE T. TUTTLE read a paper on

CASES OF MELANCHOLIA,

which is printed in full on page 77.

DR. WEBBER said he saw these cases generally in the early stages. His experience with opium had been favorable, but he had not used it in many cases. He generally preferred valerianate of zinc and hyoscyamus, in one case he had added bromide of potassium. The prevailing tendency is to give chloral and bromide of potassium, but they may do harm when long continued. A combination of bromide of potassium and hyoscyamus often seems to be of service in melancholia.

In answer to a question as to the formation of an opium habit, the reader said that the patients do not know what they are taking, and the dose is usually reduced to a very small quantity before they leave the hospital. He had not known any bad effects from the drug.

DR. STEDMAN spoke of a case of melancholia lasting three months. The patient was twenty years old, and the attack had been caused by over study. Chloral and bromide of potassium in large doses had been tried without benefit. Opium given three times a day and a generous diet proved to be the best thing.

DR. FISHER said that he used narcotics less than twenty years ago, when opium was the standard treatment. In many cases the relief is very great at first, but often they seem to be injured by the morphia, and may sink into a condition of dementia. In one case where no sleep could be obtained without morphia suicide had followed; in another case the opium habit was formed. It is always necessary to keep the patient under hospital control until the morphia is discontinued. Sometimes a solution of quinine may be substituted for it, the same quantity of liquid being taken at each dose. He thought that often more harm might result from omitting than from using the morphia, and he was inclined to think that since the treatment with chloral and bromide had been in vogue the reaction against opium might have gone too far.

DR. COWLES said that the cases cited by the reader included all the cases of agitated melancholia that had been seen at the hospital for the past four years. The main reliance has been a general supporting treatment. The authorities disagree on the advisability of using opium. Many German and French writers advise it, other French and English authorities condemn the use of sedatives. In agitated cases that go on badly after five or six months, it is well to use morphia or other sedatives vigorously. In some cases where cannabis and bromide are used early, and the insomnia is controlled, the patient is better able to get the benefit of the general treatment.

DR. FOLSOM said that there was still some difference of opinion in regard to the opium treatment of melancholia. From his experience he is inclined to think that opium has but little effect on the disease, but for a sedative to relieve the symptoms it is better than anything else. Many cases get well in two or three months if no harmful treatment is used. Business

men often work off an attack by giving up their occupation for one or two months, or by diminishing their amount of work; others, where the attack is more severe with specific delusions, may get well in from half a year to two years; but here the opium cannot be used continuously without doing harm. In epileptics opium is hurtful when used continuously, but may be safely given for periods of a few days. Many cases of melancholia that he sees have been taking bromides, bromidia, etc. The first step is to omit these, give ol. morrhuæ, malt, open air exercise, and many hours in bed; the amount of exercise must be adapted to each individual case, and must not be overdone, as too much is as bad as too little; sleep may also be encouraged by taking food during the night. In exceptional cases, where the delusions are severe and distressing, less harm will often result from opium than from allowing the patient to go without it. At Danvers he has seen a number of cases treated without opium with good results; it is not unusual to have two cases in eight recover. He mentioned the case of a young lady who had severe melancholia, with the delusion that she and all the family were to be killed by persons waiting outside the house. She had been taking bromide and chloral. These were discontinued, and Vichy, malt, and out-of-door exercise were prescribed. At the end of four months she was well. No sedatives were used, and the recovery seemed more complete and rapid than it might have been without these remedies. In answer to Dr. Bowditch, he said that he had known cases where the opium habit was acquired, but they were less frequent now than formerly.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, M. D., RECORDER.

Thursday evening, December 27, 1883. The President, Dr. Tyson, in the chair.

FRACTURE OF THE BASE OF THE SKULL.

Exhibited by Dr. Guy Hinsdale.

J. H. W., aged fifty, fell on the ice December 8, 1882, striking upon the stone pavement. The blow was received on the posterior and left side of the skull, and the skin was not broken. He was shortly afterward admitted to the Episcopal Hospital, and was totally unconscious. Blood was found flowing from his mouth and left ear, and his nose contained clots. His pupils afforded no evidence of his condition, because of an iridectomy which had been performed on both eyes some years previous. He talked incoherently; breathing was labored and at times stertorous. Paralysis of the left leg was noted.

Blood continued to issue from the left ear, and on the second day the discharge became thin, and continued serous until his death, which occurred on the eleventh day. The urine was examined several times, and found to contain sugar in moderate amount, but no albumen. Urine was passed freely. The patient never regained consciousness; he became more stupid, and paralysis of the left leg remained.

At the autopsy a superficial clot was found over the brain beneath the seat of injury. A very large clot was found over the right frontal region beneath the membranes, and filling the sulci between the convolutions. This was the result of the counter-stroke, the force having been first received at a point diametrically opposite, and fully accounts for the left-sided paralysis. The fracture was slightly over five inches in length. It extended from a point in the left occipito-parietal suture one and a half inches behind the temporal bone, and traversed the suture, passing through the petrous portion of the temporal bone, the auditory canal, close to the inner side of the foramen ovale towards the foramen rotundum, where it terminated.

NECROSIS OF THE TEMPORAL BONE AND BRAIN ABSCESS.

Exhibited by Dr. Guy Hinsdale.

This specimen was removed from the body of M. P., aged forty-six, who died in the Episcopal Hospital September 21, 1883, after long-standing aural disease.

In early childhood she had scarlet fever; this was followed by aural catarrh, and the discharge from the ear continued until her death. She stated that when twenty-two years of age a polypus could be seen in her ear. Fifteen years ago this was removed; again masses were removed thirteen years, two years, and one year, ago.

In May, 1883, four months before her death, the patient consulted Dr. Burnett, who has very kindly furnished me with notes of that date. The patient presented at that time a most wretched appearance. Extreme weakness, pallor, and emaciation betrayed the intense suffering of this unfortunate woman. Paralysis of the right side of the face had occurred during the previous winter without the supervention of additional ear symptoms. At the time of examination she presented great sensitiveness of the auriculo-temporal nerve, and complained of intense pain over the right temporal bone. To control this pain she was accustomed to use morphia suppositories. An examination of the ear revealed a mass of granulations filling the entire lumen of the auditory canal, half an inch from the entrance. Late in May a large polypoid mass was extracted; bare bone was then discovered on the posterior portion of the canal, the channel narrowed and blocked with granulations. About two fluid ounces of blood escaped after removing this mass.

When I saw the woman at the hospital in September she was in a very low state, and evidently near her end. Her mind was seriously affected, conversation was impossible, and she groaned with the pain, which large doses of morphia would not altogether control. There was a moderate but constant purulent discharge from the ear and from a sinus which was found above the meatus. The whole temporal region was boggy. The probe passed in freely over an inch, and loose particles of dead bone could be everywhere felt. The disease had long been beyond the reach of any remedy, and there was nothing to be done but relieve pain and await her death.

The specimen removed embraces portions of the right temporal, parietal, and occipital bones. Almost all the temporal bone has been destroyed. Only the mastoid process and the upper border of the squamous portion remain. An area of bone one and a half by two inches has entirely disappeared. Adjacent to this region, and lying next the middle fossa of the skull, was a brain abscess, the walls of which were greatly thickened. On opening this cavity about an ounce of thick yellowish pus was found. A probe easily reached this cavity through the auditory canal and the sinus above it, and many loose fragments of bone were found at the outlet. The styloid process was found loose, but held

in position by the various ligaments that arose from it. The inflammatory process, in which the meninges had of course shared, was not acute; the brain substance beyond the abscess walls had no unusual appearances, and the left cerebral lobe with its membranes were normal.

DR. C. H. BURNETT thanked the Society and Dr. Hinsdale for the opportunity of seeing this very interesting specimen, and of making a few remarks upon the case. The great destruction of bone tissue is remarkable and unusual in extent, being three inches in length and one and a half to two inches in breadth. The necrosis seemed to have originated in the tympanic region rather than in the mastoid, and hence belongs to the class of cases second in frequency, the most frequent being those fatal cases where the bone disease originates in and extends from the mastoid cavity. The case when seen by Dr. Burnett, in the spring of 1883, presented very grave symptoms, and the patient was extremely weak, so much so that Dr. Burnett was surprised that she lived until September. The occurrence of extensive granulations in the external auditory canal constituted a very unfavorable feature, as they acted like a dam, preventing the escape of the products of inflammation and held them back in the tympanic cavity and mastoid cells, forcing them to break an escape through more important and vital tissues. The case furnishes another example of the evil of neglect of purulent disease of the ear. Dr. Burnett inquired whether there were symptoms of destruction or implication of any of the nerves passing through the cavernous sinus, as would be shown by alteration in parts supplied by the oculo-motor, the pathetic, and ophthalmic nerves.

DR. HINSDALE replied that no eye symptoms had ever been detected.

CASE OF PHTHISIS WITH EMPYEMA.

Presented by DR. H. M. FISHER.

The patient, J. C., aged twenty-one, was admitted to the Episcopal Hospital March 17, 1883. The following notes of the case were taken by Dr. George M. Boyd, the resident physician. Patient states that he has had a slight cough for one year, but was not much annoyed with it until about one month ago, when he was seized with severe pain in the left chest, accompanied by chilly sensations and difficulty of breathing. Upon admission he presents all the symptoms of left pleural effusion, absent vocal fremitus, tubular breathing, and bronchophony in the neighborhood of the spinal column on the left side. His chest was tapped on the morning of March 21st, and three pints of a semi-purulent fluid were evacuated. The operation was followed by great improvement in the patient's symptoms. Three weeks later he left the hospital, contrary to advice. He was readmitted April 20th, and stated that, soon after leaving the hospital, the pain in the side returned, followed by dyspnœa. April 23d paracentesis thoracis was performed by Dr. Henry, and fifty-six ounces of purulent fluid were drawn off, and the operation again afforded great relief. A violent fit of coughing followed the withdrawal of the canula. The heart's apex beat was found, before the operation, to be immediately below the right nipple; after the operation it was found to have shifted one inch to the left of its previous position. May 5th Dr. Forbes operated at Dr. Henry's request, making two openings into the left pleural cavity, one at fifth interspace, the other at the fourth and to the right of the first. Ten ounces of purulent fluid were withdrawn by means of the aspirator, and a soft rubber catheter was passed in at one of the openings and out at the other. The pleural sac was then ordered to be washed out daily with a solution of corrosive sublimate, one grain to the ounce.

During the summer the patient's general condition seemed for a time to improve; his appetite, however, continued obstinately bad, and he had constipation alternating with diarrhœa. In October it was noted that he was losing flesh and strength rapidly, and that there was much œdema of the feet and legs. During this month diarrhœa became a constant symptom, and death occurred November 22d.

Post-mortem Examination (ten hours after death). The body is extremely emaciated. The left lung is contracted to about one fourth of its normal size, and contains in its upper lobe some cheesy masses with areas of catarrhal pneumonic infiltration. The left pleural cavity contains about five ounces of ichorous pus. The parietal layer of the left pleura is so tightly adherent to the chest wall that it is impossible to detach it without dissection. The pulmonary layer is also tightly adherent to the contracted left lung, the lobes of which are firmly matted together by adhesions. The right lung also presents numerous cheesy foci with large areas of catarrhal pneumonic infiltration. The heart is rather small, and its tissue is pale, but its valves appear normal. The liver weighs six pounds six and one half ounces, its tissue is pale, and it has a *markedly waxy appearance*. The spleen is much enlarged, its tissue *firm, and of a dusky-red hue*. Numerous *yellowish white nodules* are also seen in it, the largest of which is perhaps of the size of a small pin's head. The kidneys are rather large, their capsule is non-adherent, and their tissue rather paler than normal. Numerous *minute whitish nodules* are also found to be scattered through the tissue of both kidneys. These appear rather more numerous and larger in the cortical portions, but are also found in the medullary portions. From some of the larger nodules a whitish puriform substance can be squeezed out with the blade of the knife. With the naked eye the exact nature of the above-mentioned infiltrations of the spleen and kidneys is difficult to determine. Nothing abnormal was noticed in the intestinal tract, except in the ileum, where an area of intense congestion was noticed about one yard from the ileo-cæcal valve, but no ulceration was anywhere detected.

My view of the sequence of pathological events in this case is the following: First, catarrhal pneumonia with the production of cheesy foci; secondly, scrofulous inflammation of the pleura with attendant exudation, which from the start was probably more or less purulent; and thirdly, the infiltration of the *liver, spleen*, and possibly also the *kidneys* with amyloid matter.

The exact nature of the yellowish white nodules in the spleen and kidneys being yet undetermined, I cannot yet assign to them a positive place in the chain of scrofulous processes, but from the absence of any microscopic evidence of embolic infarctions, or of any appearance of infarction in the one microscopic section of the kidney I had the opportunity of examining (kindly made for me by Dr. Henry), I should conclude that these were also cheesy foci, and their production may perhaps have nearly coincided in point of time with the production of the cheesy foci in the lungs above alluded to.

Dr. Shakespeare said that specimen was a good instance of miliary tuberculosis. The small collection in the spleen might be tuberculous, he thought, and should have been examined for tubercle bacilli. He adverted to the successful employment of very weak solutions of corrosive sublimate in washing out suppurating serous cavities.

ATHEROMA, DILATATION, AND ANEURISM OF THE AORTA; ATHEROMA OF SOME OF ITS BRANCHES; DEATH FROM RUPTURE OF THE ANEURISM INTO THE LEFT PLEURAL CAVITY; CONGENITAL DEFORMITY OF THE STOMACH; MALPOSITION OF THE TRANSVERSE COLON AND RIGHT KIDNEY; IRREGULAR SHAPE OF THE KIDNEY; ANOMALOUS ORIGIN OF THE RENAL ARTERIES AND OF THE URETERS.

By J. H. Musser, M. D.

This remarkable series of specimens illustrates how serious a disease can be in progress within the body without any manifestations. The patient had been under the care of Dr. Ludlow in the Presbyterian Hospital, complaining of, and being treated for, nasal catarrh. He complained, also, of a slight bronchitis, but, it not being very decided, the nasal trouble alone was treated. A white man, aged sixty-three, well nourished, of temperate habits, and by occupation a wheelwright. He was under observation ten weeks. No previous illness. He slept well the night before his death until five A. M. He then told the night nurse he was very cold. Being covered, he went to sleep apparently; an hour afterwards he was found dead. The writer made the autopsy about twelve hours after death.

Inspection. Rigor mortis well marked; body well nourished; no scars or bruises; no ecchymoses; abdomen moderately distended; in the right lower quarter a decided swelling was noticed, almost filling that area and resonant on percussion.

Section. Abdominal cavity first examined. The above-described swelling was due to the cæcum and transverse colon. The ascending colon extended about half way the usual distance and then turned at a sharp acute angle into the transverse colon. The latter descended parallel to the former into the right iliac fossa, and from thence diagonally upwards across the abdomen to the usual place of junction with the descending colon. The omentum contained a considerable amount of fat. The right lobe of the liver could not be seen until removal of the ribs, when it was found two inches above their margin and to be only two and one half inches in length in the nipple line. In the median line this same perpendicular length was three and one half inches. More of the left lobe was visible than the right. Along the edge of the left lobe, from the median line, four and one half inches in length, extended the *stomach*. It appeared to be small in size. When removed it was found to be divided by a constriction five inches from the fundus; from this constriction to the pylorus the length was four and one half inches. The first or cardiac end was much smaller than normal, the walls and mucous membranes healthy. The second portion was a mere tube with thick walls. The thickening was due to the hypertrophy of the longitudinal muscular layers, and to the folds that the mucous membrane was thrown into. These folds were very marked, longitudinal, and, on their crests, congested. The peritonæum was opaque and thickened. The *liver* was smaller than usual also. The capsule was thickened and opaque along the edges of the right lobe; on examining surface there were cicatrices and a firm adhesion at one point to the diaphragm. On section the tissue was firm on pressure, and congested. Commencing cirrhosis noted on microscopical examination. The gall-bladder projected one inch below the liver margin in the nipple line.

The left *kidney* was found in its normal position. It was much enlarged, five inches long, two thick. The pelvis was filled with fat, the substance pale, hard on pressure, with a contracted cortical portion. The capsule tore off easily. The right kidney was found in the pelvis at the right sacro-iliac articulation. It was small in size, irregular in shape, parallel to the sacrum. The portion dipping downwards tapered to a point, being one half inch in width; the upper portion was two inches wide. The pelvis of the kidney was filled with fat. Towards the small end of the kidney the hilus divided, one part extending upwards one inch along one side of the organ, the other the same length on the other side; or it might be said, a portion of the kidney dipped into the pelvis, separating it for an inch. The renal artery arose from the normal origin of the middle sacral. One inch from the point of origin it divided, one branch, one inch long, entered one lateral hilus, if it may be so termed, the other divided two and one half inches from the main trunk, one subdivision entering the remaining lateral hilus, the other running across the floor of the pelvis to the normal end of the kidney. The ureter arose in three branches — two from the upper end, one from one of the smaller pelves.

Thoracic cavity. Left pleural cavity almost filled with blood, the lung floating on the fluid. The lateral surface was adherent to the aneurism. In its removal the collapsed sac was seen on the left side of the vertebral column. The heart and aorta were removed entire. Heart enlarged, left side especially; measurements of left ventricle: round base, one and one eighth inches thick, in the middle, seven eighths inch thick, at apex, one half inch thick; mitral valves a little thickened; aortic healthy. Atheromatous processes were present in the aorta from its beginning to the cœliac axis, and extended into the latter vessel and also the innominate and carotid arteries. One calcareous plate was found in the cœliac axis. From its origin to the middle of the transverse aorta the vessel was dilated, and the characteristic fatty changes of the proliferated cells of the intima, lemon-yellow colored, smooth, soft elevations, were marked. Opposite the trachea the calibre of the aorta diminished to almost normal size, and here the sclerotic changes were most marked as well as around the mouths of the vessels. At the junction of the transverse and descending aorta the lumen was again closed. Here the aneurism originated. It was five and one half inches long, and, where distended, twelve inches in circumference. It was of the true variety, but from it sprung four false aneurisms, varying in size from a filbert to a small egg. Organized clots covered the surface of portions of the wall. Rupture of the sac took place behind and in pleural adhesions, and leaked into the cavity, finding its way through the adhesions. The vertebræ were not eroded, and although the sac was in contact with the left bronchus there were no evidences of decided pressure upon it, while the relations to nerves, other vessels, and the œsophagus were such that the usual pressure symptoms could not arise.

It is thus seen that by physical examination alone this aneurism could not have been detected. There were absolutely no subjective symptoms, and the autopsy reveals the reasons of this.

HOUR-GLASS CONTRACTION OF STOMACH. CONGENITAL.

Presented by J. H. MUSSER, M. D.

The patient, an adult, from whom I removed this stomach, died of organic heart disease. Constant vomiting occurred a few months before death, but as a consequence of the general condition of the patient, and not on account of the gastric change. I call the appearance congenital because of the absence in the clinical history of any occurrence throughout life to have caused it, and of the want of evidence on post-mortem inspection. The contraction took place in the centre, and was transverse. The peritonæum and submucous connective tissue was thickened at this point. Anterior to the constriction the muscular coating was hypertrophied. The mucous membrane was thrown into folds by the constriction.

LUNG FROM A CASE OF PLEURO-PNEUMONIA COMPLICATED WITH DELIRIUM TREMENS.

Presented by J. H. MUSSER, M. D.

I present this specimen to-night on account of its perfection. It is the lower lobe of the right lung in the stage of red hepatization, as indicated by the appearance, weight, etc. Almost the entire pleural surface, including the diaphragmatic, is covered with recent lymph, the layer averaging one half inch in thickness. The tongue of the lung dipping into the space between the diaphragm and the thoracic wall is not solidified entirely. Here the lymph is abundant, and the contiguous portion of the lung hepatized, as if the inflammatory process extended from the pleura. This peripheral hepatized portion is but one fourth inch wide. The inner and succeeding portion is not solidified.

The patient died eighteen hours after admission to the hospital, from heart-clot. When admitted there were evidences of its formation, and in addition he had the delirium tremens. The pneumonia was distinctly recognized. There were no signs of simple or diaphragmatic pleurisy. At the autopsy on removing the sternum, the extreme distention of the right heart, was remarked, especially the auricle. On opening the heart, hypertrophied from other causes, the right side was found filled with blood, and an enormous antemortem clot entwined around the leaflet of the tricuspid valve and extending through the auricle into the pulmonary vessels. A similar clot was found in the left heart. The kidneys were congested, and commencing cirrhosis appeared manifest.

The history of the case antecedent to the admission to the hospital is as follows: The patient had been on a "spree" for two weeks, and five days before admission had had a severe chill followed by the symptoms of pneumonia. Two days after the chill the mania developed, and on the day of admission he had been found wandering about the streets by a crony, who brought him to the hospital. He was forty-one years old, a boss machinist, single, of intemperate habits.

CARCINOMA OF THE UTERUS; FATTY KIDNEYS AND EMPYEMA.

By W. A. EDWARDS, M. D.

The specimens which I show you to-night were taken from the body of A. E. this morning. I have not, as yet, had the opportunity of examining them microscopically. The patient was visited but once before her death by Dr. J. S. Watt, for whom I made the post-mortem examination. The history of the patient is of course imperfect; in fact, little if any could be obtained; the symptom of which she complained the most was an ill-smelling, irritating discharge from the vulva, so our attention was first directed to the womb, which presents a scirrhus carcinoma of the external and internal os and of the cervical canal. The mucous membrane of the organ is softened and very rugous, looking not unlike a mammillated stomach. A microscopic section will probably show cellular infiltration. The uterus is enlarged; our subject was a multipara, aged forty-five, nine children and two miscarriages. A cyst was seen in the right parovarium, its contents was pure serum. The ovaries presented areas of calcareous degeneration; other pelvic viscera normal. The kidneys are small, and appear to have undergone some amyloid change; the right one was a rib higher than its normal position.

Heart muscle has undergone some fatty degeneration as has also the aorta; valves almost normal, antemortem clots in each ventricle, that in the right is of unusual size. Pericardium contained the usual straw-colored effusion.

Lungs: Left normal. Right, the pulmonary and costal pleura were in many places adherent by thick, well organized lymph, which beautifully illustrates the rationale of friction râles, their sudden appearance, short duration, and equally sudden disappearance. About a pint of purulent effusion was collected in the base of right chest. The diaphragmatic pleura was tightly adherent to the pulmonary, requiring some tearing in order to separate. The lobes of this lung are bound down by recent lymph. Scattered throughout the mesentery were to be seen areas of calcareous degeneration, about the size of almonds.

Recent Literature.

Wiesen as a Health Resort. WISE. London: Baillière, Tindall & Cox. 1883. 68 pages.

This little book is an evidence of the growth in favor of high altitude in the treatment of early phthisis. Davos and St. Moritz have become fashionable, and consequently expensive, but consumption and the desire to be rid of it are not confined to the rich. Wiesen, moreover, seems to have some special advantages in situation apart from its cheapness. It is eleven miles from Davos, and about three hundred feet lower, but lies on a hill-side, about one thousand feet above the river, while Davos is in the valley, and but little above the river level; while equally protected from cold winds by mountains, Wiesen is, therefore, dryer than Davos. Full details are given as to the best means of reaching these Alpine sanitaria, at the same time that the visitor is advised as to clothing and informed as regards accommodation, food, resources for passing the time, physicians' fees, and the like. At the end of the book unusually full meteorological tables are inserted, doubling its thickness if not its value. A special table shows the cases of death since 1834, and from this we learn that if any inhabitant of Wiesen ever died of consumption he brought no discredit to his native place by dying there. The writer evidently wishes to

be fair, and we can recommend his book as containing useful information alike to those who think of seeking health for themselves in the Alps in winter, and those who send others in the search thither. F. C. S.

Medical and Surgical Journal.

THURSDAY, JANUARY 24, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE HEATING OF DOMICILES.

THE problem of how best to heat our dwellings is (be it said without a quibble) a burning question. Many plans have been suggested, some of which have erred by premising that methods which have been found sanitary and available in England, for instance, would be equally feasible in our country. This has been the mistake of those who have advocated the open fire-place, or its congener, the open grate, as a sole means of heating. In England and in many Continental countries these methods have proved sufficient. But any one who has tried to warm a New England house by means of the time-honored and æsthetic hearth and andirons has discovered that he has burned up a small fortune, but has not succeeded in making his house thoroughly comfortable. The fire-place, excellent ventilator as it is, and useful adjuvant to other calorifacient agents, cannot be depended upon to entirely *heat* a house in this climate. Only twelve per cent. of the heat value of fuel thus burned is rendered into the room, the remainder passing up the chimney. Even were one to burn an open fire in every room, which is hardly practicable, there would be many draughts felt in cold weather at the further portions of the apartments, for air must be drawn in from without to supply the constantly ascending current, and it is known that a considerable transmission of air takes place through stone, brick, and plastered walls. So that in freezing weather the occupant of a house thus heated would be subjected to constant risk of colds from draughts as well as from too low a general temperature.

At the opposite extreme from the open fire, as an economist of fuel, stands the close stove, which gives out into the room seven eighths of the heat which the fuel produces, and loses an amount only equal to the small proportion which the open fire-place saves. Yet while it warms it admits no fresh air to the room, and takes but little foul air out. It is now generally admitted that heating and ventilation should be combined, and that that system is best which introduces an abundance of pure, warmed air into the living apartments, and removes the exhausted air. Another objection to stoves is the increased care and expense of maintaining a separate fire in each room. Preference is therefore given to some general system which warms all rooms from one common centre either within or outside the house.

The two rival methods are the furnace and steam heat.

In the February number of the *North American Review* we find a discussion between representatives of these two opposite methods. Dr. A. N. Bell, known to some of our readers as the editor of the *Sanitarian*, presents the claims of the furnace as, on the whole, the best system of heating the average moderate-sized dwelling. It is noticeable, however, that his requirements for the furnace are by no means fulfilled by most specimens of that article found in the market.

He lays emphasis on (1) a chimney draught stronger than that in the hot-air pipes so that all gaseous emanations which may be caused by crevices in the joints or a cast-iron pot which becomes overheated may be drawn off through the chimney.

(2.) The draught should be all from below the grate, with no dampers in smoke-pipe or chimney.

(3.) The fire-pot should be lined with fire-brick, and while entirely within the furnace, yet separate from it so that the fresh air to be warmed cannot come in contact with the fuel chamber.

(4.) The cold air should always be taken from out-of-doors, and the shaft should be turned up on the outside several feet from the ground, covered with iron netting and a cotton dust-strainer, and the diaphragm for controlling the ingress of air be placed at this point rather than in the cellar.

(5.) The inlet shaft should be at its smallest part, of an area amounting to one sixth of a square foot for every pound of coal estimated to be burned hourly in cold weather; and the collective area of the hot-air pipes should not be more than one sixth greater than that of the cold-air inlet. This last precaution is to prevent one hot-air pipe from drawing its supply of air from another, an accident which is not uncommon when the cold-air box is not large enough.

(6.) The heating surface should be large. As a rule there should be ten square feet of heating surface to every pound of coal consumed per hour in active combustion. The grate area should be one fiftieth of the heating surface.

Prof. W. P. Trowbridge, who is an advocate of steam heating, makes strictures on the furnace system, some of which are forestalled by the precautions that Dr. Bell inculcates. His principal argument is that the furnace heats the air to a temperature of from 250° F. to 400° F., and that by mixture with cold air it is brought down to 150° F. or 200° F. at the time it enters the rooms. Of course it requires further admixture with cool air, for which reliance is put upon accidental leakage from doors and windows. These highly heated currents of air have a great capacity for absorbing moisture from all sources. It is just at this point that the great and vital objection to most furnaces lies. Air that has once been heated to 300° F. or 400° F. is not fit to breathe. The device of setting

water to evaporate in the heating chamber is, in our opinion, comparatively useless. Such air when admitted to a room has a peculiarly dry and irritating character. It warps doors and other wood-work, shrinks the joints of furniture, withers plants, and dries up the mucous membranes of the occupants. It certainly seems not unreasonable to attribute a considerable proportion of the nasal catarrhs, ophthalmias, and winter colds of the community to such causes instead of laying them all to the account of "our wretched climate." A few years ago the theory was advanced that this depraved state of the air in furnace-heated rooms was due to the use of cast iron in contact with the flame, and accordingly wrought-iron furnaces came into the market. Dr. Bell evidently shares the prejudice in favor of brick-lined pots, but the radiating surface above the flame must be of iron, and, if we remember right, Professor Remsen concluded, as the result of some experiments conducted on this point, that the purity of air exposed to superheated metal was no greater in the case of wrought than of cast iron. At all events the practical point to be guarded against in furnaces is the *overheating* of the air, and this we understand to be the object of most of Dr. Bell's directions.

There are two methods of steam-heating, the direct and the indirect. In the former the steam is led from the boiler to a coil of pipes in the room to be heated, called a radiator. From this augmented surface the heat is diffused into the room. The principle involved in this method is not materially different from that of stove heat. Both warm by radiation from a hot surface without bringing in any fresh air. One important difference (if it were a question of preference between steam radiator and stove) is that the pipes are never heated by the steam to a temperature higher than from 210° F. to 310° F., while a stove may become heated in extreme cases as high as 950° F. The element of ventilation can be added, though imperfectly, to direct steam radiation, at some sacrifice of heat, by placing the radiators near windows, and letting in out-door air under the sills to be heated and then diffused over the room. By the second or indirect method the steam is conducted from the boiler to a close chamber, which is directly under the tier of rooms to be heated. Here the pipe makes a coil, and to it is admitted fresh air in large quantities from out of doors. This air is warmed to a less degree than by any other method, say to 70° F. or 100° F., and is then delivered directly to the rooms in large quantities by pipes and registers. The comparatively low temperature of the current is economically in part counterbalanced by the increased amount of heated air thrown into the room, and by the fact that the pipes ascend almost directly, and do not lose heat, as in the furnace, by being carried horizontally, as each stack of pipes is supplied from its own radiating chamber directly underneath it.

In conclusion it may be said that wherever the boiler can (as a precautionary measure) be placed outside the building to be heated; wherever the building is so large as to require more than one furnace, if the furnace were used; wherever the heat must be transmitted to a considerable distance horizontally from its source; or wherever a number of apartments can be heated from one common centre, the indirect steam system is to be preferred. But that for the average dweller in a detached house of moderate size this system, as at present arranged, cannot be expected to become popular on account of the increased original expense of the "plant," the slightly greater intelligence necessary to understand, and skill to operate it, the liability to condensation of steam when the fire runs low, and the "pounding" which is caused when the newly-formed steam drives the water in the pipes, and which occasionally produces explosions or leaks. Finally, that in most cases where the expense of the steam system cannot be incurred, a sufficiently safe method of heating is by the furnace, care being taken to introduce a large quantity of pure out-door air to the furnace chamber, and thence into the rooms, and to see that this air is not allowed to come in contact with over-heated metal; moreover that the open fire-place is a most useful addendum to the furnace system by affording a means of escape for vitiated air, and thus maintaining a constant current through the apartment.

IS THERE A NON-CONTAGIOUS ERYSIPELAS?

THE contagiousness of erysipelas would seem to be established clinically beyond a doubt. Striking instances in abundance are narrated in our text-books of the spread of the disease in families and hospital wards which it is unnecessary to repeat. The presence of micro-organisms in erysipelatous tissues has been abundantly established, and Dr. Fehleisen, of Berlin, has recently published the results of experiments undertaken to determine whether a species of bacteria peculiar to erysipelas is regularly demonstrable, and if this is so to inquire whether this micro-organism stands in an ætiological relation to the disease. A micrococcus, identical with one figured by Koch, was found in each one of eleven cases examined. To demonstrate that this was a specific organism and not merely accidental, attempts were made to cultivate it outside the body. After numerous failures the micrococcus was at length successfully cultivated upon Koch's meat-peptone-gelatine, and fourteen generations were produced. Though somewhat similar organisms are found in the pus of wounds and in pyæmia the mode of growth of the micrococcus of erysipelas was found to be characteristic. Experiments were first made upon rabbits to test the question whether, when inoculated, it would produce genuine erysipelas. Nine were inoculated on the tip of the ear with the cultivated micro-organisms, and in eight a typical erysipelas was produced. Inoculations of the cultivated bacteria were also made upon the human subject. An accidental attack of erysipelas has proved beneficial in such diseases as cutaneous tumors, lupus, and carcinoma, and in six cases of this sort the experiment was deemed justifiable. In each of these cases the characteristic symptoms were developed after an

incubation of from fifteen to sixty hours, and it was felt that no room for doubt remained that inoculation with Fehleisen's cultivated micrococci had for its result the production of a genuine erysipelas; the specific nature of the contagium and the contagiousness of the disease would seem to be established.

Thus scientific research seems to enforce clinical observation in regard to the highly contagious character of the disease. But there is another set of opinions, based on clinical study, diametrically opposed to the opinions referred to.

Mr. T. Holmes, in a letter to the *Lancet* in May last, wrote: "It has always seemed to me that erysipelas, though no doubt under some circumstances contagious, is very feebly so, and that when it spreads in a hospital it does so in consequence either of carelessness in nursing or of impurities in the wards far more frequently than from contagion. In fact I have never myself seen a case in which I could trace contagion."

Dr. Goodridge, Physician to the Bath Royal United Hospital, writes in the *Practitioner* of December, that after a pretty long experience in a provincial hospital, where cases of erysipelas have always been admitted into the ordinary medical wards, he has never known the disease spread from bed to bed.

Billroth speaks of the disease as propagated by a contagium which is considerably less infectious than that of measles or scarlet fever.

In view of these opposing beliefs Dr. Goodridge is led to ask whether there are not two distinct forms of disease classed under one head, as from superficial resemblances, which may be very close, diseased conditions are apt to be confounded together which yet are fundamentally distinct. His personal experience strengthens this view. He has been the victim of three attacks of erysipelas of the head and face. Of these the first and third were distinctly infective. In the second case, which followed exposure to the sun, there was no constitutional disturbance. The case presented all the usual naked-eye features of erysipelas but without the tendency to spread, and resolving without delay, was clearly an instance of simple, non-infective inflammation, a simple dermatitis. He is led to the conclusion that in cases of facial erysipelas as they ordinarily present themselves in practice, whatever secondary varieties may exist, there are primarily two distinct forms to be dealt with, namely, the infective and the non-infective forms, or as the distinction, it will be seen, may otherwise be expressed, true genuine erysipelas and spurious or pseudo-erysipelas. "Without venturing to indicate in what ratio these two forms stand to one another as to frequency of occurrence, I am quite sure that I have again and again seen and treated cases of the latter — cases in which the local affection has followed exposure to heat or cold or other injurious influences, and the fever and general disturbance have been comparatively insignificant." Mr. Jonathan Hutchinson, in his paper On Certain Diseases Allied to Erysipelas clearly recognizes their existence when he says: "These forms of erysipelas which are due to local irritation are, I think, almost always mild. It is when the disease is due to contagion that it assumes its greatest severity."

The question is not a new one. It must have suggested itself to many. In 1871 Maurice Reynaud suggested that septic principles differing one from the other might possess the common property of producing the local and general accidents of erysipelas. Such an idea would explain so easily "how all cases of erysipelas are far from possessing the same degree of gravity, how some are contagious although others are not." It would seem that in time the researches in the line followed by Fehleisen would solve the question.

MEDICAL NOTES.

— We have reason to believe that a man, sometimes pretending to be deaf and dumb, is falsely representing himself to be an agent for the Journal, in common with other medical periodicals, in the States of Indiana and Michigan. We have at present no *traveling* agent in those States.

— "At one end (of the salon), in huge electric letters, I saw the words, 'Welcome, restored old patients;' at the other end, 'Dr. Pierce, the Hotel Founder;' in the centre of one long side, 'Golden Medical Discovery;' and along the ceiling, also in electric letters, 'Purgative Pellets.' . . .

"'And now,' said the Queen of Health, 'let me present you to my prime minister.' Timed with her gesture to the right, I turned my eyes, and there saw, in evening costume, a robust gentleman, of medium stature, who was in physique the very ideal type of American manhood. He seemed the very embodiment of healthful, vigorous vitality, and on his full, lofty brow I saw great indications of comprehensive mental power, sweet benevolence, unvarying courtesy, tender sympathy, and business sagacity. . . .

"I saw two venerable, sweet-faced men of Grecian features approaching the Queen of Health, holding in their hands two wreaths of evergreen — the veritable laurel from the Athenian groves. She stepped from her throne, as complaisant monarchs do, and raised them to her dais. Another bugle for silence, and she spoke: 'My guests, before we sup, an interesting ceremony remains. He on my right is Hippocrates from the Spirit Land. He on my left is Æsculapius. They come to crown our Dr. Pierce with the great laurels of his noble profession — they the great Past Grand Masters of the Healing Art, who best know who is conqueror of disease.' In a moment Dr. Pierce was about bending his knee in respectful obeisance to these ancient professors, when a gesture from both arrested him, as with dainty but dignified motions they placed upon his head the laurel leaves, each saying in a unison of musical monotone, 'Thou art our legitimate successor,' while a burst of orchestral acclaim and a chorus of thanksgiving huzzas from the guests arose. Immediately above this royal and supernaturally looking tableau I saw in pillars of rosy light these great words, the motto of the crowned Dr. Pierce, and which

reveals the secret of his almost divine success, 'THE BLOOD IS THE LIFE.'"

The above we publish as a specimen chapter. The remainder will be found only in the advertising columns of — well, we are ashamed to say, of a *Review*, which for over a half a century has occupied a foremost place in American literature. The rhapsody is ascribed to an American girl abroad, but the suggestion occurs that she wrote it when about half way on her passage thither.

— On February 1, 1884, the New York Post-Graduate Medical School, at which, since its foundation, 140 students have availed themselves of the vast amount of clinical material placed at their disposal, will take possession of more commodious accommodations located in East Twentieth Street. This change is the more advantageous as the building to be occupied is of such proportions as to admit of increased attendance on the part of both students and patients.

— The *Medical Times and Gazette* comes to us in its first issue for 1884 in an enlarged and much improved form. Its table of contents indicates a high order of excellence, and in general this periodical is evidently to become, if it is not so now, one of the most useful of the English medical publications.

— We learn that Secretary of State Frelinghuysen, having determined to establish in Egypt a system of inspection and disinfection of rags destined for the United States, has communicated this intention to the Boston Board of Health and asked its views as to the propriety of such a course, and also suggestions as to the best method of purifying rags. The Board has replied, heartily approving the plan, and suggesting Dr. George M. Sternberg, Surgeon, U. S. A., as an authority on disinfectants.

— The *International Review of Medical and Surgical Technics*, the official organ of the American Association of the Red Cross, a new quarterly journal edited by Dr. Joseph H. Warren, has reached us in its initial number. Its aim is to present a description of the principal instruments and appliances described in American and foreign journals.

— Dr. John Taylor Gilman, of Portland, Me., is dead at the age of seventy-eight. He was a prime mover in the establishment of the Maine General Hospital, and was president of the Maine Medical Society in 1864.

NEW YORK.

— Up to the 18th of January the contributions to the Hospital Saturday and Sunday fund had reached the sum of $37,742.08. This is nearly $8000 more than the entire amount contributed last year, and it is probable that a considerable sum yet remains to be reported.

— Dr. Henry A. Du Bois, who died on the 13th of January at his residence in New Haven, was formerly well known in New York, where he was born, and where he spent a considerable portion of his life. He was graduated at the College of Physicians and Surgeons in 1830, and after spending some time as an interne at the New York Hospital went to Europe, where he remained for three years studying under the most distinguished masters of medical science in London, Paris, and Edinburgh. On his return, in the latter part of 1834, he at once took a high position among the physicians of the city, and became especially prominent during the scarlet fever epidemic of 1838, when he won an honorable notoriety by taking a firm stand against the severe antiphlogistic treatment which was then in vogue. He recognized the disease as a self-limited affection, which it was impossible to cut short by any heroic measures that might be adopted, and devoted himself to supporting the system with quinine and a highly nutritious diet until the fever had run its course.

— A tobacco merchant of New York died at his home in that city on the 13th of January, of yellow fever. He had been in the habit of often making business trips to Cuba, and during the month of December spent eighteen days in Havana. He reached New York January 7th, and the next day he was attacked with yellow fever. A favorable issue was anticipated, however, until the morning of the day he died, when he was seized with uræmic convulsions. The autopsy, at which Prof. E. E. Janeway, Dr. J. B. Taylor, Chief of the Fourth Sanitary Division, and several other physicians were present, confirmed the diagnosis of yellow fever.

PHILADELPHIA.

— Two new associations are in process of gestation at present. During the present month a Committee on Permanent Organization of the Philadelphia Neurological Association will report in favor of forming a society for the study of neurological science in all its departments. The officers of the insane hospitals in this neighborhood will form a part of the membership.

A society for the study and advancement of Forensic Medicine will also be formed during the next few weeks. A number of prominent names both in law and medicine has been secured; and the association will be instituted under very favorable auspices.

Correspondence.

SALT ON STREET RAILWAYS; ITS MEDICO-LEGAL ASPECTS.

MR. EDITOR, — Having been asked some time ago by the presidents of some of the Boston horse-railway companies to make investigations as to the hygienic effect of sprinkling salt on tracks covered with snow or ice, I feel impelled, now that the subject has been brought before the medical public, to present the position of these corporations, whose servants, by the anomalous action of the Boston Board of Health, are now being subjected to petty prosecution, with risk of imprisonment when detected, in performing an act against which there is a total absence of trustworthy authority or facts establishing any prejudicial effects either upon the health of the public or of animals. The position thus taken by this sanitary body not only exposes it to unfavorable criticism from physicians, but

tends to weaken confidence in its judgment on the part of those in whose favor it is supposed to act, namely, the fair-minded public. Johnson somewhere says, when discoursing upon physicians, that when people see a man absurd in what they understand, it is not unnatural or unreasonable that they should be distrustful of him in what they do not understand.

This comparatively trivial subject is not beyond the comprehension of the laity, who will not long suffer unnecessary interference with whatever contributes to its convenience; nor should the protests of a minority, who may suffer from wet feet inadequately protected, nor even of those whose heavy teams are liable to become stuck upon the bare tracks, be allowed to hamper the efforts of the railway companies, who spare no expense in the work of clearing tracks and removing snow from the streets, and who should not be liable to official annoyance on grounds not fully established.

When so much undisputed sanitary reform demands their attention, local boards should surely confine their attacks to nuisances plainly, unquestionably, and substantially injurious to the public health; and should not allow themselves to enact, in opposition to the highest authorities, an arbitrary ordinance against a merely hypothetical evil; but such an ordinance having been thus passed, it follows that under this pseudo-sanitary code the Board of Health, as is naïvely said by a correspondent (in the JOURNAL of the 17th inst.), "have not found it difficult to furnish the necessary evidence to convict the violators of the salt order." It is possible that his confidence in equal success in the future may prove unfounded, should the railway authorities deem it advisable to carry the question to a higher tribunal for decision on its merits. That such an appeal has not hitherto been made is solely in order to avoid a conflict with a Board which has in the main decided wisely and for the public good.

There is nothing new to advance on this subject, which has been thoroughly and frequently investigated both in this country and in England. The indisputable facts are, that the weight of trustworthy evidence is overwhelmingly in favor of this use of salt under proper restrictions, *as a sanitary measure*. The writer who (in the JOURNAL of January 17th) says that he had supposed "that the mingling of salt and snow produced an intensely cold and corrosive mixture, which not only must be directly injurious and uncomfortable to the feet of horses," etc., furnishes a fair instance of the dogmatic and unsupported assertions which have given rise to the erroneous impressions by which the Board of Health seems to be influenced.

Salt under no circumstances is capable of producing a *corrosive* effect upon animal textures, nor can it be absorbed by the unbroken skin, and it is only slightly irritant to the mucous membrane or to abraded surfaces. Were the reverse true, the first to suffer from this fact would be the horse-railway companies, whose horses are constantly exposed in full force to whatever danger might exist; but, on the other hand, at their annual meeting, held in Chicago, October, 1883, the combined testimony, based on extensive personal observations, affirmed that no evil effects whatsoever have been detected in consequence of the distribution on the tracks of salt, which, on the contrary, from its astringent, cleansing effects, constitutes, in the form of salt baths, one of the best applications for the relief of "scratches" and other inflammatory affections to which horses' feet are liable.

And yet it must be admitted that this practice is open to abuse, as was shown by a somewhat unfortunate experiment tried in this city some years ago in the use of refuse salt which had served in packing hides or fish. The result was, that after the salt was washed away there remained a putrefying animal substance, offensive to sight and smell, and capable of producing mischief when brought in contact with an open crevice or wound in a horse's hoof. An obvious nuisance was herein promptly recognized, and the assurance given that the offense would not be repeated. Another and a frequent source of trouble is due to the failure on the part of the city authorities to keep clear the crossings, gutters, and entrances to the sewers, thus causing an unnecessary accumulation of water, which may form pools of considerable extent along the tracks; but for this delinquency the railway companies should in no way be held responsible, having, as in the past month, urgently protested against it, and done all in their power to remedy it. When, however, an opportunity is afforded for the mixture of salt and snow to run off, it disappears more rapidly than pure melting snow, thus flushing the sewers with a saline disinfectant which has been recommended in England as an efficient sanitary measure in case of epidemics.

The snow and ice having accumulated in large quantities, it is inevitable that there shall follow a season of slush and standing water, which may *per se* affect injuriously men and animals forced to wade through it; and it would seem almost superfluous to suggest from a hygienic stand-point that a process which curtails this disagreeable period is a beneficial one. Moreover, in the weak solution formed by the combination of snow or ice with salt in the proportion commonly found on or near the tracks, the result of experiments has shown a reduction in temperature of from 1° F. to 5° F. only; and this depression is but temporary, continuing merely while the snow is actually melting.

Again, as a matter of fact, it cannot be gainsaid that it is indispensable to public safety that salt mixed with gravel in sufficient quantity to dissolve the thin film of ice which forms recurrently on the steel rails be used to prevent the slipping of the car at such times, the force of the brakes being insufficient to control it on a downward grade when the wheels no longer revolve. Without this precaution, in itself a violation of the present ordinance, the cars may not be safely run for a single day over tracks thus coated; and through its neglect severe accidents have already occurred, for which the companies have been held liable. The *London Sanitary Record* goes so far as to advise the distribution of a moderate admixture of rough salt with water from ordinary watering-carts over all main thoroughfares covered with ice and snow, in order to facilitate traveling and lessen damage and suffering to horses; maintaining that the conducting power of the earth and the absorption of heat from neighboring objects prevents such a solution when not confined within an inclosed space from materially lowering the temperature of the surrounding atmosphere. This view is fully sustained by Prof. R. E. Rogers, M. D., of Philadelphia, who experimentally demonstrated that at an elevation of three feet above the ground the atmosphere is not rendered perceptibly colder by the use of salt.

Much more literature on this subject might be quoted in favor of the railway officials, who feel that their position is still further strengthened by the sup-

port of the best sanitary authorities in this vicinity (outside the City Board); but space permits only the following from an editorial in the *London Sanitary Record:* "We have always supported this proceeding (salting the roads in winter), the alleged scientific medical reasons against it being mere superficial, half-informed twaddle. . . . To salt the snow and dissolve it, and then sweep it down the drains, is the only natural and economical way of dealing with it."

ARTHUR H. NICHOLS, M. D.

ROXBURY, *January* 21, 1884.

"SALTED TRACKS."

MR. EDITOR, — It is a satisfaction to have it from highest authority that "Boards of Health and others who have considered the matter prefer the salt water for streets in summer on account of being cheaper than fresh water, doing better service, and being a good antiseptic." We had so argued long ago. Now that it is settled there need be no further discussion or doubt on that point, and the practice may continue without let or hindrance.

It is also satisfactory to have it from the same authority that "the salt and snow or ice make a freezing-mixture in which no one can long stand or walk with ordinary protection without loss of comfort or danger to his health." This, then, is the whole of it, — to "long stand or walk" on "salted car tracks?" But why do it? Why not take to the sidewalks, which are presumably freed from snow and ice, or otherwise protected? No one is obliged to stand or to walk long *in the street* on salted or clean car tracks. Avoid so doing; and, according to S. H. D., inferentially, health is not compromised.

At last Boards of Health "prefer the salt water for streets." Possibly (stranger things have happened) it may not be long before objections may cease to "salted tracks" on the score of public health; when, under efficient city government, crossings may be properly cleared, and "ponds of salted slush" quickly cared for, while those long standing, at the risk of health or comfort, in such unsafe places are gently told to "move on."

The foregoing is all that is fairly deducible from the varied comments on our previous question, which remains as yet unanswered. Really, the case appears much weaker than anticipated. The premises adduced do not warrant the conclusions, and juries which convict on such "evidence" must be swayed by prejudice or misapprehension. On the point raised the writer finds himself still uninformed and as much as ever

NESCIENS.

BOSTON, *January* 19*th*.

AN EXTEMPORIZED ICE-BAG.

MR. EDITOR, — Having occasion a few days ago to make use of an ice-bag, and nothing of the sort being obtainable, the wits of the family were set to work to find a substitute. The result of these cogitations was the suggestion of an expedient which, though ridiculously simple, is so thoroughly practical that I make no apology for asking you to mention it in the JOURNAL. The credit of the suggestion is due a young lady in the family, who brought me a rubber gossamer cloak and asked if I could not use the hood. This was immediately filled with snow, and did as good service as if it had been made for the purpose.

Very truly yours, R. A. KINGMAN, M. D.

BOSTON, *January* 18, 1884.

Miscellany.

MORTALITY STATISTICS OF PROVIDENCE, R. I., FOR THE YEAR 1883.

FROM the report of deaths during the year 1883 by the City Registrar of Providence we take the following figures: Two thousand three hundred and twenty-eight (2328) persons died in Providence during the year 1883. This number was eighty-six more than in the previous year, or an increase of 3.83 per cent. The increase of population in the same period was 4.39 per cent. The 2328 deaths in 1883 represent an annual rate of mortality of 19.50 in each 1000 of the 119,405 inhabitants of the city. The rate in 1882 was 19.60 in each 1000.

Ages. There were 666 decedents under five years of age in 1883, or 28.60 per cent. of all. The number and percentage of decedents under five years of age in each of the last four years have been as follows: —

	1883.	1882.	1881.	1880.
Number under five years of age .	666	678	727	731
Percentage	28.60	30.24	33.89	35.14

The number and percentage have been growing less in each of the last four years.

Between twenty and fifty years of age there were 698 decedents in 1883 and 718 in 1882; between fifty and seventy years there were 429 in 1883 and 351 in 1882; and of seventy years and over there were 330, or 14.17 per cent., in 1883, and 286, or 12.75 per cent. in 1882.

PUBLIC PROSECUTORS AND PRIVATE PERSECUTORS.

OUR English brethren are, with reason, considerably stirred up over some recent suits which have been brought against two surgeons, Messrs. Bower and Keates, by the father of a child on whom tracheotomy had been performed by the defendants in diphtheria to avert impending asphyxia. At a meeting held at the residence of Sir Wm. Jenner Dr. Moxon detailed the circumstances as follows: —

"It appeared that two suits had been brought against the unfortunate gentlemen; one a civil action, brought by the father of the child to recover damages from Messrs. Bower and Keates because he had been instructed by them, after the operation of tracheotomy had been performed, to suck the tube, which had become obstructed, and thereby to save the life of his own child. The father subsequently had some slight throat affection, which, it was thought, was probably of a diphtheritic nature, though it was certainly not severe diphtheria; and it was to recover damages for this that he brought the action. The first trial terminated by the disagreement of the jury. A new action had been commenced, and this part of the matter was therefore *sub judice*, and could not be discussed at present. After the failure of the civil action, although it had been given in evidence in the course of the trial

that the parents had no complaint to make concerning the treatment of the child, and, indeed, were completely satisfied therewith, the mother proceeded to swear an allegation at the Lambeth Police Court, stating that the treatment of the child had been improper, and charging its medical attendants with manslaughter. This charge was taken up by the Public Prosecutor, who conducted the action on behalf of the Crown. It might appear scarcely credible that this high public functionary felt justified in undertaking the criminal prosecution of these gentlemen for the manslaughter of their patient without one atom of medical evidence before him in support of the charge. The result of the examination of the defendants before the magistrate was the dismissal of the charge immediately after the cross-examination of the medical witness summoned on behalf of the prosecution, — the magistrate remarking that this was a case of 'persecution,' not prosecution."

The especial point of complaint made by the profession was that the Public Prosecutor should have lent the authority of his position to the complainants without having investigated the validity of the grounds on which the action was based. A resolution was offered at this meeting by Sir James Paget, and seconded by Dr. Wilson Fox, "That the Council of the Royal College of Physicians and the Council of the Royal College of Surgeons be requested to consider the propriety of representing to the Secretary of State for the Home Department that it is very desirable that there should be some arrangement by which the Public Prosecutor may obtain the assistance of skilled advisers when he is solicited to institute prosecutions of medical practitioners."

Subscriptions to defray the heavy legal expenses of the defendants were made to the amount of £200 at the meeting, and it was proposed that the amount of individual subscription be limited, so that the whole profession might have an opportunity to express their sympathy with the defendants in a persecution to which any medical man was liable to fall a victim. We learn that these contributions have been very liberal, already amounting to more than the legal expenses of the accused.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 12, 1884.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2693 (no reports from New Orleans, Buffalo, and Charleston): under five years of age, 950: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 472, lung diseases 434, consumption 380, diphtheria and croup 179, scarlet fever 73, typhoid fever 57, diarrhœal diseases 39, measles 48, malarial fever 26, whooping-cough 18, cerebro-spinal meningitis 17, erysipelas 16, puerperal fever 13, small-pox one. From

measles, Baltimore 15, Brooklyn 12, District of Columbia 11, New York seven, Philadelphia three. From *diarrhœal diseases*, New York 13, Brooklyn nine, Boston six, Baltimore three, Chicago two, Cincinnati, District of Columbia, Milwaukee, Nashville, Cambridge, and Springfield one each. From *malarial fever*, New York nine, Baltimore five, St. Louis three, Brooklyn two, Chicago and Cincinnati one each. From *whooping-cough*, New York and Baltimore five each, Chicago and St. Louis two each, Brooklyn, Boston, Salem, and Chelsea one each. From *cerebro-spinal meningitis*, NewYork six, Philadelphia three, Chicago and Boston two each, District of Columbia, Milwaukee, Lowell, and Worcester one each. From *erysipelas*, New York five, St. Louis three, Chicago two, Boston, Baltimore, Providence, Lowell, Merrimac, and Wrentham one each. From *puerperal fever*, New York three, Chicago, Cincinnati, and Milwaukee two each, Boston, St. Louis, New Haven, and Weymouth one each. From *small-pox*, Philadelphia one.

Thirteen cases of small-pox were reported in St. Louis, Cincinnati one; scarlet fever 50, diphtheria 36, typhoid fever five, and measles one in Boston; scarlet fever 12, and diphtheria in Milwaukee.

In 90 cities and towns of Massachusetts, with an estimated population of 1,284,384 (estimated population of the State 1,922,530), the total death-rate for the week was 17.41 against 18.00 and 21.05 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending December 29th, the death-rate was 20.6. Deaths reported 3397: acute diseases of the respiratory organs (London) 355, measles 109, scarlet fever 104, whooping-cough 80, fever 55, diarrhœa 23, small-pox (Birmingham and Liverpool four each, London two, Sunderland one) 11. The death-rates ranged from 15.5 in Bradford to 25.8 in Newcastle-on-Tyne; Bristol 17.2; Plymouth 17.4; Birmingham 18.4; London 19.8; Sheffield 20.7; Nottingham 21.7; Birkenhead 22.4; Leeds 23.2; Liverpool 24.9; Blackburn 25; Manchester 25.4. In Edinburgh 19.5; Glasgow 24.3; Dublin 27.5.

For the week ending December 22d, in 155 German cities and towns, with an estimated population of 8,091,113, the death-rate was 23. Deaths reported 3577; under five years of age, 1120; consumption 511, lung diseases 377, diphtheria and croup 273, whooping-cough 67, scarlet fever 60, typhoid fever 55, measles and rötheln 54, puerperal fever 31, small-pox (Danzig one) one, typhus fever (Breslau one) one. The death-rates ranged from 12 in Karlsruhe to 38 in Königsberg; Breslau 28.2; Munich 28.2; Dresden 26.5; Berlin 20.9; Hamburg 21.8; Cologne 24.5 Frankfort a. M. 17.8.

For the week ending December 29th, in the Swiss towns, there were 26 deaths from consumption, lung diseases 24, diarrhœal diseases 16, diphtheria and croup eight, scarlet fever six, whooping cough two, erysipelas two, small-pox (Basle two) two, typhoid fever one. The death-rates were, at Geneva 13.3; Zurich 16; Basle 19.3; Berne 29.4.

The meteorological record for the week ending January 12th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

TWO CASES OF INJURY TO THE BACK.[1]

BY CHARLES F. FOLSOM, M. D.,

Physician to Out-Patients with Diseases of the Nervous System, Boston City Hospital.

Among the cases in my note-books I find quite a considerable number where injuries, especially falls, producing quite severe blows upon the back alone, upon the head, or upon the back and head together, have been the apparent cause of grave symptoms, involving the mind or the general nervous system, or both. I find that the gravity of the resulting disease does not depend upon the severity of the primary injury, nor upon the intensity of the pain and other indications of mischief immediately following. The character of the disorder, whether spinal, cerebral, or general, has not in these cases depended upon the locality of the original disturbance, whether of the head or of the back. Of two cases of delusional mental disease, one, which resulted in recovery, was, I think, the direct outcome of a fall in a skating-rink, whereby the back of the head received a sharp blow not causing even momentary unconsciousness. The second was slowly developed through slight mental confusion, irritability, hardly distinguishable change of character, suspicion, jealousy, and fear of personal injury into delusional mental disease, remaining now, in the fifth year, an incurable insanity, which originated in a succession of violent blows to the back, but no injury to the head, from falling down stairs.

A large number of cases of epilepsy and a few cases of general paralysis of the insane were thought to have been the direct consequence of blows or other injuries, for the most part of the head, but to a less extent of the back. Chorea, too, and the group of symptoms classed under the head of spinal irritation, neurasthenia, and now and then hebephrenia, had their origin associated with the same immediate cause.

I learn from the notes that in the majority of cases in the individuals in whom concussion (not using the word in its technical sense) of the brain or spinal cord, or both, in my judgment, produced symptoms which would be commonly called mental or nervous, there was a hereditary predisposition to the neuroses or psychoneuroses, or that there was a developed instability of the nervous organization; but that fact does not by any means universally hold true. There is a vast preponderance of females over males, but the most difficult case to care for, and the longest to get well under what I thought to be judicious treatment from the beginning, was in a strong, able-bodied, intelligent man, who had been vigorous enough to frustrate an attempt to garotte him, but who, in the process, fell backwards, striking his head, neck, and shoulders on not very hard ground. This man had the greatest variety of manifestations of general disorder which I have ever seen classed under the heads of hysteria, railway spine, etc., and he was two years in regaining sufficient health to go to work, although he had the stimulus of the necessities of his wife and children to make him do so, and although any possible litigation upon the subject was so early decided that there was every inducement to him to recover. His cure has seemed a thorough one for now over a year. I have been long convinced that many of these patients were suffering quite as much from disease affecting the brain as from anything which could with propriety be named hysterical, or spinal, or nervous, and many of them wholly from such disease.

The cases which I shall report to-night are two, in which quite similar injuries, producing nearly identical primary indications, resulted in widely different pathological conditions calling for directly opposite methods of treatment.

Miss ——, sixteen years old, a bright, very large, robust looking girl, brought up in a country town, came to me with her sister, giving the following history: She belonged to a family in which there were several members considered nervous, but in which no case of the neuroses or psychoses had appeared. She had never had any severe illness, and had always been healthy and strong until three months previous to consulting me, when she fell very heavily, striking her back on a level with the upper lumbar vertebra. She became somewhat dizzy, but not strikingly so, although feeling weaker than usual for a few days. The pain was disagreeable, and increased by moving about much, so that she was compelled to keep quiet for several weeks. After that time she was told that she had spinal disease, and her parents were informed that she must be treated as an invalid the rest of her life, the tenderness and pain at the seat of the injury still persisting. She was told that she must lie down much of the time, but that she might come to Boston to attend school, provided she did not walk or stand or study very much. I ascertained that the lungs, heart, and kidneys were free from evidence of disease. The patient began to menstruate in her fourteenth year, and the function had gone on without any indication for interference. The appetite was moderate. Digestion was well performed, barring an habitual constipation, which was readily overcome by careful regulation of food and habits. There were absolutely no indications of disordered function, except the pain and tenderness already referred to, a sense of weariness, and backache for the greater part of the day, a slight loss of flesh, and a progressively increasing loss of strength. The patient's sister had been directed not to allow her to sit long, to dance at all, to walk more than a very little, or to take part in the usual gymnastic exercises of the school. In fact, she was in the process of being trained to become an invalid of the neurasthenic type.

After the usual examination I felt satisfied that there was no real injury to the spine or brain, that there had been only a bruise, and that the treatment called for was not unlike that found most successful in a sprained ankle, when the acute symptoms had gone by. The sister was directed to follow out a course of treatment of which this is the outline: —

A dash of cold water the whole length of the spine, followed directly by a sponge bath every morning. General massage once a week, and rubbing of the muscles of the back, shoulders, and abdomen every evening. To begin gymnastics with a view to strengthening and giving tone to the muscles supporting the weight of her heavy body at the end of a week, and in two weeks to take up dancing, at first very moderately. She was to practice at the piano, of which she was fond, a half hour each day, with a full support to her back, and she was to lie down for half an hour fifteen minutes after her back began to ache, but never to continue work with an aching back.

[1] Read before the Boston Society for Medical Improvement, January 14, 1884.

The sister was directed to inform me as to the progress of the treatment, the inmates of the house were recommended to look upon the young girl as in no way an invalid, and the patient was told not to come and see me again for a month, thereby getting additional assurance from my statement that there was no serious trouble with her. In a little over three months she has become quite well, she walks, dances, and seems quite like the other girls in the school.

The second case belongs to a class much more difficult to deal with.

Miss ——, aged twenty-six, an intelligent, healthy-looking, high-school taught Irish American, with a comfortable home in one of the suburbs, where she kept house for her father and sister. She did not know of any mental or nervous disorder or any so-called nervousness in any of the branches of her family. She has been told that at the age of six or seven years she had pleurisy, and when fourteen slow fever. Otherwise she has been quite well and strong, and the picture of physical health. She began to menstruate at the age of fourteen, and has from the beginning suffered from intense dysmenorrhœa. During the previous winter she had been up late and early, and her sisters thought that she had been overworking. She was not herself conscious of any weariness or feeling of effort. Her mind had been quite at rest. She had no anxiety, and had not lost flesh, and she was quite contented with her lot in life. She seemed to me exceptionally fortunate as regards the complicated circumstances combining to affect her general health. Last February she fell, striking her sacrum on the ice. The pain and discomfort from the blow were not great, so that she walked home and did not find it necessary to in any way diminish the labor of her daily life. For three weeks there was decided tenderness when lying on her back, and only slight pain at other times, which then disappeared. She noticed, however, that her daily work wearied her, and so she had walked out less than usual. Four weeks after the accident, in trying to walk a distance to which she had formerly been accustomed, she remarked a dull ache through the right thigh with decided weakness, and finally difficulty in walking. This symptom remained without abatement until August, when attempting to walk, the weakness of the leg rather increasing than diminishing, so that she then went to the sea-shore for a fortnight without benefit. Upon her return the leg began to ache in its whole length if used, so that she walked about only a little, and sat sewing much of the time. Then the arm began to ache and to feel weak. There was also about the same time a steady uncomfortable feeling in the head, always disagreeable, never severe.

She came to the out-patient department of the City Hospital September 19th, asking for the room for the treatment of nervous diseases. She was well formed, healthy looking. Her father had taken her to the horse-cars, and she found great difficulty in getting from Washington Street to the hospital, a distance of, perhaps, three hundred yards. The heart, lungs, and kidneys were ascertained to be healthy; the appetite was fair; bowels constipated; and there had been a slow but progressing loss of flesh, in all amounting to about five pounds. She slept poorly. There was a constant feeling as if the brain had been bruised, which was not much increased by mental effort, but any work requiring thought or planning produced a sense of general fatigue over the whole body. The emotional state was much exalted. The patient could not sit long in the waiting-room without excessive fatigue and great increase in the pain affecting the extremities. She thought her mind was weakened, as she could not bear things at home with her customary equanimity. I could not find anything abnormal from an examination of the head, ears, or eyes. The ophthalmoscope was not used. The patient complained of a great ache, rather than pain, throughout the right arm and leg, and in the right side of the chest. The whole fore-arm sometimes felt as if encased in ice. A severe pain appeared at different times in different spots of the upper arm and thigh, and there was a feeling of numbness at the seat of the injury, sometimes very troublesome, oftener hardly noticeable. Between the shoulders, over a space ten inches in diameter, quite nearly symmetrical, and involving both sides, was an area of burning-heat sensation, varying in intensity under conditions for which I could not find any approach to a law. Sensation was slightly impaired pretty much throughout the right side, but there was at no time any marked anæsthesia. The arm could scarcely be used in any of the ordinary duties of life, and the leg was exhausted after quite moderate efforts. There had been a sense of muscular spasm without any visible movement as observed by the patient in both legs, much less in the left, but also in the right arm.

In such a case as this healthy occupation and diversion for the mind are of the first importance, so that isolation and the rest cure were not to be thought of. A feeling of introspection and self-consciousness was particularly to be avoided, so that a hospital was distinctly contra-indicated on account of the danger of establishing a chronic invalidism. I saw no reason for removal from home except for convenience of treatment, and that could not be afforded, and yet the home was not a favorable place for the care of a sick person. I doubted whether massage would be of use, and my experience of other similar cases led me to question whether it might not do harm. At all events it was not procurable.

She was directed to walk only as much as was necessary to get to the hospital three times a week, her father driving her to the horse-cars; to use the arm only a couple of minutes at a time, at long intervals, and then for no fine movements. She was not to read or do anything involving mental effort except in a general way to direct her sister about the management of the house. She was to be taken out of herself as much as possible. From week to week she was allowed to gradually increase the amount of physical and mental work as she found she could bear it, and I soon ascertained that she was better those days when she came to the hospital than when she remained quietly at home. The faradic brush was used over the arm of a strength just beyond what could be comfortably borne for a month. At the end of a month's time all the most disagreeable symptoms in the arm had disappeared, and in a month more it was quite well except that it had still to be used carefully. The leg remained stationary, or, if anything, getting worse for a month, while the arm was improving, so that the patient was directed to apply the faradic brush to the whole length of the leg, since which time improvement has begun. With malt, cod-liver oil, and hypophosphite of lime four times a day the general condition improved, there was a slight but continuous gain in

flesh, the sleeplessness disappeared, and in a month and a half the uncomfortable feeling about the head had gone, to return only for a short time at considerable intervals. I dare say that the daily cold affusions to the back helped to improve the general condition, and had something to do with the rapid subsidence of the dyspnœa, panting breath, sensation of constriction about the chest, tightness about the heart, and paræsthesias. As soon as the head began to feel well iron was given, at first in very small doses, and later the acid phosphates and arsenic. The constipation has been regulated by diet and mild laxatives.

At the present time the mental state has returned to the normal. The arm is quite well but not fully strong, the head does not cause any trouble or uneasiness, the abnormal sensations have gone except the pain in the thigh, although that has improved, and the strength of the leg is constantly mending. I confidently expect a full cure within three to six months. But the element of time seems to me extremely important in these cases, and I think that careful treatment should be insisted upon for at least six months after apparent recovery, to enable the system to entirely regain its tone.

I know of no way in which the physician can form an opinion as to the extent of the damage done by injuries to the back and head except by reserving his prognosis for quite a time in order to see which set of symptoms appears. There probably will be a difference of opinion among equally qualified men with large opportunities for observation, as to the extent to which rest should form an important part of the immediate treatment of even seemingly trivial accidents causing a physical shock to the brain or the spine. Doubtless evil results happen less often than others. But serious trouble comes not seldom, and incurable, almost life-long, suffering is not uncommon in cases where there will always be at least a doubt whether sufficient care in the beginning might not have averted a tragedy. Whether in the first of these two cases the severe pain necessitated the rest which saved the young girl from the development of more serious disorder, and whether, in the second, the mildness of the initial symptoms encouraged the activity which prevented a speedy cure are questions of interest to the physician, and of importance to the patient. My own experience leads me to treat all similar cases with great caution from the beginning.

THE USE OF TOBACCO BY BOYS.[1]

BY EDWARD O. OTIS, M. D. (HARV.)

ONE might deem an apology almost necessary for adverting again to the trite subject of the use of tobacco, a subject which has been discussed almost from time immemorial, and of which so much true and false has been said. Still it is a fact that tobacco-using among boys is common, and, further, most medical men, I think, will admit that the use of tobacco by boys, either moderately or immoderately, is injurious. So long, then, as this is the state of things it may not be amiss to raise one's voice from time to time against the abuse. Although not much that is new upon the matter may be presented, every agitation against an evil does something towards eradicating it.

I propose to leave out entirely any discussion of the effects of tobacco, injurious or otherwise, upon adults, and refer only to its use by boys.

My attention was especially directed to this subject while in practice at Exeter, N. H., where I met with many of the students of the Phillips Exeter Academy, and noted the effect of tobacco upon them. I became still more interested by reading — through the kindness of the late principal, Dr. A. C. Perkins — a large number of letters sent by parents, teachers, and others in response to a circular letter of the principal asking their opinion regarding the use of tobacco by boys in the school. To the circular and letters I shall refer later on.

As to the exact percentage of boys who use tobacco there do not seem to be any very accurate statistics. At the academy above referred to I should say that at least one half of the students used it. The statement was made some time ago, I believe in a secular paper, that seventy-five per cent. of school-boys over twelve or thirteen years old smoke cigarettes. I am inclined to believe that this is too high. At the Boston Latin School, of those in the upper classes from fourteen to eighteen years of age, the head master stated last year that probably about half used tobacco to some extent. The principal of another school stated that since his connection with it the number of smokers had nearly doubled. This is enough to show that the evil prevails extensively, and gives good reason for serious apprehension.

Whatever injurious effects the excessive and constant use of the drug may have upon adults, these are more marked and intensified in the case of the youthful user of tobacco; and, moreover, the youth are more inclined to its use to excess, for theirs is an age of immoderation. For example, a young student, from fifteen to seventeen years of age, I should think, told me he was smoking about a bunch of cigarettes a day, and although promised a trip to Europe if he would abandon the habit, said he did not think he could do it even for that prize. It is a time of rapid change, physically and mentally, with them; there is a constant development going on, and although I am not aware that any careful series of observations have been made, still I am sure that the general observation of all is to the effect that tobacco interferes with and retards the proper symmetrical development both of mind and body. Of course there are exceptionally robust and strong boys who, although they use tobacco, mature into sturdy men with good minds, but it is in spite of the tobacco. The especial deleterious effects of tobacco upon the young are pretty well known from all the discussion and much exaggeration that has been rife about them. I will briefly mention some of them.

There is the so-called "tobacco heart," an irregular, irritable heart. Dr. Gihon, in his report on the United States Naval Academy, says, "The annual examination of cadets reveals a large number of irritable hearts among the boys who had no such trouble when they entered the school." This was before tobacco was prohibited at that institution.

Another effect is defective muscular coördination, as shown in the tremulousness of the hand in manipulating a pencil or pen, and inability to draw a perfectly straight line. The professor of drawing at the Naval Academy said that he could invariably recognize a

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, December 12, 1883.

user of tobacco from this inability. I myself observed the same thing in the case of a young man who smoked continually.

Besides impeding mental growth it is an obstacle to mental application and effort. It is said to produce progressive deterioration of the intellect, and to impair its integrity. At the instance of Napoleon III. a commission was appointed to examine the young men in the government training schools of France as to the effect of tobacco upon them. The students were divided into two classes, the smokers and non-smokers. The former were found so inferior, physically, mentally, and morally, that the use of tobacco was prohibited in all the schools under governmental supervision. In the École Polytechnique it was found that the non-smokers took the highest rank in every grade, and that the smokers continually lost grade.

The principal of a boy's school near Boston stated that the habit of smoking was more prevalent in the lower classes than in the upper, the reason being that the smokers were usually the poorest scholars, and were gradually weeded out as the class advanced in the school. In one of the letters above referred to the writer says: "If a successful salesman to whom I was paying a high salary should begin the use of tobacco, I should feel that about fifteen per cent. of his vitality or ability was taken from his usefulness, and hence should be taken from his salary."

It is said to impair the memory. In another one of these letters, the writer somewhat graphically relates the effect of tobacco upon his memory, as follows: "I commenced the use of tobacco when thirteen years old, both smoking and chewing. I went to school but could not study, had no ambition at all to learn anything, and it was almost as well not to learn, since I could hardly remember anything from one school to the next. . . . The most lasting injury is the fact that tobacco ruined my memory, which does not come back to me, although I have not used tobacco for fifteen years." Another writer says that there is a young man in his factory twenty-one years old, powerfully built, and weighing one hundred and eighty pounds, brought up on a farm, who uses tobacco. Years ago he noticed a loss of memory, and a diminution of vitality generally.

It is a well-known fact that tobacco may cause defective vision. Dr. Gihon in the report above referred to says: "I have myself several times rejected candidates for admission into the academy on account of defective vision, who confessed to the premature use of tobacco, one of those from the age of seven." I have noticed that the mechanical irritation of the smoke, especially from cigarettes, which bring it so near the eyes, will produce and keep up catarrhal trouble. I have a suspicion that tobacco used as the boy is emerging from boyhood into manhood causes an undue irritation and excitability of the sexual system, prompting to abuse and excesses.

Then there is the irritation of the mucous membrane of the mouth and throat, impairment of digestion, sometimes, an habitual sense of uneasiness, palpitation, hypochondriasis.

With regard to cigarette smoking by boys, I will refer to two paragraphs from an editorial on the use of tobacco in the *Boston Medical and Surgical Journal* for November 23, 1882: "The number of young men who smoke cigarettes is almost startling. It is not only students but even school-boys in their teens who vigorously and openly indulge in this dangerous habit." And again: "The dangers, then, which are incident to cigarette smoking are, first, the early age at which it is taken up; second, the liability to excess; and third, the bad custom of inhaling the smoke. These are dangers superadded to those attendant on the ordinary use of tobacco, and should be carefully considered by all medical men."

Dr. Witter, of Grand Rapids, Wis., in a paper in the Report of the State Board of Health of Wisconsin for 1881, among the conclusions which he deduces from a large number of letters written on the subject by physicians of the State, says: "That beginning the use of tobacco in early life cannot be too strongly condemned as producing most pernicious effects upon the constitution of the young, and as impairing greatly, if not wholly destroying, the chances of success as students and scholars."

The evil effects, then, of tobacco upon boys which can be said to have been fairly proved by observation, are: —

First. An interference with and impairment of the general development, physically and mentally. Probably it does this by retarding progressive cell change, and impairing nutrition. In an adult the development is attained, consequently he can smoke with impunity so far as this effect is concerned, when the boy only does it with injury.

Second. The tobacco heart. This likewise happens to the adult, but is, I should think, more likely to happen to the youth, and with graver result, because his is such an unstable age physically. For this same reason the other injurious effects are more liable to be intensified in the youth.

Third. Defective muscular coördination. I have but little proof to show that this condition is more than temporary, continuing only while the tobacco is used.

Fourth. It reduces the intellectual power of the boy. It does this either by opposing mental application and effort, or else by producing deterioration of the intellect, probably both to a greater or less extent.

Fifth. It impairs the memory. What proof I have adduced seems to show that this is a permanent injury.

Sixth. It may cause defective vision, and also irritation, more or less chronic, to the external parts of the eye.

Seventh. It may unduly excite the sexual system and lead on to excesses. I have no positive proof of this, but my observation among boys rather points to it.

Eighth. Irritation of the mucous membranes of the mouth and throat, more especially in case of cigarette smoking.

Ninth. It may impair digestion, and produce other derangements, such as habitual uneasiness, hypochondriasis, and so on.

One cannot reason as to the effect of tobacco upon boys from its effect or lack of effect upon the mature man. The conditions are different. It would be quite as reasonable to say that, because to a sick man a certain drug is administered with good effect, the same drug may be administered to a well man with no evil effect.

If what I have said is true or approximately true, it would seem eminently wise to do what we can to keep tobacco from boys. It is a pity to allow them unwittingly to do that which may prevent their highest development physically, mentally, and morally. It is the physician's duty to expose the danger and warn parents and teachers. The latter must use their influ-

ence and authority both by persuasion and restriction. In schools, after the case has been fairly presented to the boys, I believe absolute prohibition should be enforced with all the rigor of the school authorities. I know of no greater aid to effectually bringing about this result than a good gymnasium with a competent medical director.

I am fully aware with our large freedom how many difficulties there are in the way of prohibition, but still I believe it would lead to better results than any other method, and reduce the evil to a minimum.

You cannot reason with boys, as a rule, on the matter. If you present to them all the future evils which may accrue to them from its use, that their chances of future success are so much lessened, that they may be laying up for themselves ill health, shattered nerves, and an impaired mind, they may assent to it all, and then the next moment forget it, so little do they regard the future.

What was done at the military and naval academies when the evil was appreciated, the following notes to the principal of the Phillips Exeter Academy will show:—

I. U. S. Naval Academy, Annapolis, Md., *May* 20, 1882.

Sir,—I beg to acknowledge the receipt of your letter of the 18th inst., and in reply to inform you that the use of tobacco in every form is prohibited to students of this institution.

Very respectfully, ——, Supt.

II. Headquarters U. S. Military Academy, West Point, N. Y., *May* 18, 1882.

Sir,—The officers in immediate charge of the cadets were unanimously of the opinion that the use of tobacco worked great injury, and the Academic Board was practically a unit in favor of its prohibition.

Very respectfully, your obedient servant,

——, Adjutant.

The president of one of our colleges says: "We have required our students to abstain from the use of tobacco since the founding of the college, now almost fifty years. My impression is that we would sooner lose half of our students than dispense with the rule. We never have any objection to the rule from pupils or their parents. All believe in it, but every year we part with one or more who cannot overcome the habit. We do not treat the use as an immorality, but as a disqualification for membership. We give them an honorable dismission that they may go elsewhere."

In conclusion, it may be of interest to read the circular before referred to, and give the result of the answers, a few of which I will read as giving the opinion, and often the experience of intelligent men on the subject, though most of them not medical men:—

Phillips Exeter Academy,
Exeter, N. H., *May* 15, 1882.

Dear ——,—The effect of tobacco upon boys has of late claimed the attention of many persons interested in the welfare of schools in England, France, Germany, and America. It has been the subject of discussion in our own Faculty. So far as we can learn, it is the unanimous testimony of physicians that the use of it by boys and young men is bad for mind and body. For this reason it has already been prohibited in the U. S. Naval Academy at Annapolis, and more recently in the U. S. Military Academy at West Point. In the report of the Surgeon General of the U. S. Navy for 1879 there is a careful scientific discussion of this matter by Dr. A. L. Gihon, Medical Director at Annapolis. Brief extracts from this report are sent herewith, to which your attention is respectfully called.

We should be glad to have you write to us and state what your own preference is as to the use of tobacco by boys in whom you are most interested, and also whether you would regard a rule prohibiting it entirely in this school as reasonable and practicable.

If any effort is made to suppress by school authority a practice that is working so much mischief with boys, and which yet is to many boys so attractive, we feel that the cooperation and support of parents is first of all to be sought.

You will observe that the question of the use of tobacco by adults is not touched; the inquiry relates simply to boys.

If you will give us your views upon this matter you will much oblige us and assist us in determining just the right measures to be taken with boys who are committed to our care.

Yours very respectfully, ——, Principal.

In response to this circular one hundred and sixty letters were received from parents, teachers, and others interested in the subject. Of these one hundred and sixty, all were unqualifiedly opposed to the use of tobacco by boys.

One hundred and twenty-four were in favor of prohibiting its use entirely in the school.

Ten were in favor of prohibition, if such a rule could be enforced.

Eighteen expressed no definite opinion regarding prohibition.

Eight thought a rule prohibiting it was not practicable.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

December 12, 1883. The meeting was called to order at eight o'clock by Dr. R. T. Edes, chairman.

The first paper of the evening was read by Dr. E. O. Otis, entitled

THE USE OF TOBACCO AMONG BOYS.[1]

Dr. H. I. Bowditch, in opening the discussion, said that it is high time that some measures were adopted to stop or at least to restrain the use of tobacco. For thirty years he has continually found a certain number of patients who have presented the symptoms of grave functional disturbance of the heart, for which no cause could be found excepting tobacco. There is no organic cardiac lesion, but it is a nervous weakness. This condition was very commonly observed during the late war. Nearly all the soldiers smoked, and many gradually acquired what was appropriately named the "tobacco heart." The reason why this condition prevailed so extensively at the time mentioned is no doubt found in the fact that tobacco enables men to endure hunger, cold, hardship, and privation better than they could without its aid. The active, exposed muscular life of the army enabled the soldiers to withstand the injurious effects of this substance better than would be the case in a sedentary occupation, or where one lives as a recluse. A moderate use of tobacco may unquestionably be continued for a long time, and probably indefinitely, without harm. There are few people in adult life who would derive any injury from three cigars daily; but the danger comes from the fact that the number is increased to ten or fifteen, and sometimes even to twenty-five in a day. Nearly all boys now smoke cigarettes to an inordinate extent, and it is painful to look forward to their future condition.

[1] See page 99 of this number of the Journal

In habitués of tobacco we frequently find errors of digestion, sometimes of most refractory character, though many persons commence to smoke from the supposition that the digestion is benefited by the use of tobacco. There is no question upon the fact that mental disease may be induced by the poisonous action of nicotine; and many smokers who are not insane have been rendered exceedingly nervous and irritable by the prolonged use of tobacco, and immediately give unmistakable evidences of absolute derangement if the customary indulgence is for any reason withdrawn. The duty of physicians would seem to be to endeavor to restrain the use of tobacco to an amount which shall not be injurious; for no attempt to stop its employment would probably be successful. Above all we should seek to restrict its use among students and youths generally. Punishment, such as expulsion or suspension from school, should be attached to disobedience, and all proper means should be employed to protect our scholars from its influence. The medical profession should take a decided position upon this important subject. Not only tobacco but all stimulants should be restrained to a limit within which they can do no harm. Tea and coffee should doubtless be included in the category of agents capable of harm. When in Paris in 1854 Dr. Bowditch found the favorite *café noir* to be such a nervous stimulant that he was able to work all night without the least feeling of fatigue. On returning to America, however, he found himself unable to follow his professional duties with his accustomed energy, but felt a great sense of lassitude and depression. He now reduced the use of coffee to once a day; but after three or four months he found himself subject to attacks of palpitation and cardiac pain, which recurred with considerable regularity. Dr. Jackson examined the heart, but could detect no organic lesion, and advised abstinence from coffee, upon which all symptoms at once disappeared. After a time the use of coffee was again commenced; whereupon the previous disturbances of the heart were soon reproduced. The harmful agent was again abandoned for fifteen years, when being once more in Europe, coffee was resumed in small quantity, but within a short time the old symptoms all recurred in a more intense form. Since that time no coffee has been taken, and no further trouble has been experienced The human system seems never to fully recover, after once being thoroughly saturated with any of these substances. The same is true of alcohol.

DR. GEORGE B. SHATTUCK thought it a too common habit, in speaking of these matters, to make the *abuse* and the *use* of a substance synonymous. It is also common to form general conclusions in regard to the effects of stimulants and narcotics from personal and individual experience, and to apply to our neighbors the rules we find necessary for ourselves. It is possible to be indiscreet and to commit excesses with beefsteak as with tobacco, and the individual should decide what *his* system requires. The subject of discussion before the Society, however, the speaker suggested, was the use of tobacco by *boys*; and in regard to this he felt sure that the members present would cordially agree with the paper of the reader, Dr. Otis, and with its conclusions that the use of tobacco by the immature, even in moderate quantities, is injurious and undesirable.

DR. HARLOW observed that if tobacco retards development during the years of growth, it must continue to be a harmful substance even after the body has reached its full growth, and would work injury at any time of life. If it irritates the heart in a boy, it will do so to some extent in a man. President Quincy was accustomed to advise students against the use of tobacco or stimulants while engaged in their collegiate course.

DR. MARCY stated that when a surgeon in the army he had observed occasions when tobacco was a godsend to the soldiers in aiding them to endure hardship and privation and cold and hunger. There are some organisms to which it may be of questionable benefit, but it is a serious injury to any growing person. There is no doubt that a popular vote would be largely against the general use of tobacco.

DR. PRINCE thought a distinction should be made in the form in which tobacco is employed, whether in cigarettes, or cigars, or a pipe. Cigarettes probably make a more lasting impression upon the system than cigars, and are harder to renounce. There is a popular impression that the principal injury comes from the paper containing the tobacco. This is not true. In cigarette smoking the vapor is inhaled, and coming in contact with the delicate mucous membrane of the air passages its active properties are at once absorbed, and produce an immediate effect, which can be perceived to the tips of the fingers. The succeeding sensation is one of ennui, malaise, indolence, and muscular hebetude, which soon becomes burdensome unless the stimulation be renewed and prolonged by a fresh cigarette.

DR. MARCY said that the question of the *form* in which tobacco is used is really important, if we are to judge of the *effect* from the quality of the substance employed. Many cigars are made from refuse of all kinds, which is pressed into shape and inclosed in a genuine tobacco leaf for a wrapper, while cigarettes more generally contain pure tobacco, particularly when they are made by the smoker as required for use. Certainly, as far as wholesomeness and cleanliness are concerned, cigarettes must be ranked as far preferable to cigars.

DR. LANGMAID stated that the most important questions in cigarette smoking are these: Does the inhalation of the vapor induce any disease of the mucous membrane with which it comes in contact? Does the smoke act upon the mucous membrane simply as smoke, or from the fact that it contains nicotine? Does smoking increase naso-pharyngeal catarrh? To these an affirmative reply must be given. If the mucous membrane is irritated, smoking invariably makes it worse. Will smoking produce a catarrhal state when none exists, or awaken a new one in a patient who has been cured of the disease? Observation teaches that it can do this. There is an increased secretion from the membrane, and all the other features of a catarrhal condition. Singers almost invariably abstain from smoking on those days upon which they expect to sing.

DR. BOWDITCH added that he will not treat a patient for sore throat unless smoking is abandoned for the time. He has, however, never observed any affection of the bronchial tubes as indicated by rales or other physical signs which could properly be laid to the influence of tobacco.

DR. CUTLER asked if any distinction was to be drawn between smoking and chewing. He stated that a teacher told him that students became much more stupid after smoking than after chewing tobacco. Dr. Mussey has

made the same observation in regard to the mental depression from tobacco.

Dr. Edes remarked, in closing the discussion, that the subject had been presented with great clearness and in a very unprejudiced manner. One of its excellent features was the absence of exaggeration upon a topic which is generally discussed in an eminently partisan manner. There is no doubt something to be said on both sides.

Dr. George M. Garland presented the next subject of the evening, as follows: —

THE TREATMENT OF FOLLICULAR TONSILLITIS.

Follicular tonsillitis is a self-limited disease, which runs its course in a certain definite time, presents a sequence of definite and successive phenomena, and finally returns to a normal condition in about the same interval of time, whether any active treatment be employed or not. Any treatment, therefore, is directed chiefly to minor points, such as (1) the rapidity of relief; (2) the time when the patient may return to business; (3) the convenience and comfort of the patient as far as the method of treatment is concerned, and the ease with which the remedies can be applied. The disease invariably presents itself in one of two types. First, there is a type in which the follicles are stuffed full, with swelling of the parts, general malaise, high temperature, and great prostration. The malaise lasts from twenty-four to thirty-six hours, and subsides entirely without treatment. I generally give some quinine and a gargle, because it seems necessary to give something in order to minister to the feelings of the patient and his friends, but the cure would take place equally well without any treatment whatever. In the second type there is high fever, considerable pain, prostration, and high pulse. The patient is in bed, and appears very sick. The general symptoms far outrank the amount of disease in the throat. This variety lasts from three days to a week or fortnight, running through a similar series of changes, excepting that they are somewhat more pronounced, as are observed in the milder variety of tonsillitis. The tonsils gradually return to a state of health, and the patient is cured just as in the type before mentioned. I have seen advised and have tried some of the nastiest things which can be made in the form of gargles. There is no danger attending the disease itself, there is no necessity for treatment of any kind, and above all there is no excuse for anything in the shape of disagreeable treatment of this disease by dirty and nauseous mixtures. The question of treatment rests only on the plea of shortening the disease and benefiting the patient. My plan is about this: Where the temperature is elevated to 102° F. or 103° F., I first give the patient a *sweat*. I do this by means of aconite. I prescribe five drops of the tincture, and direct that one third be taken immediately, one half of the remainder in half an hour, and the rest in an hour. I then give five grains of Dover's powder, and cover the patient warmly, up to the neck. When sweating commences I give all the water the patient desires for two hours. At the end of that time the sweating is generally pretty profuse. The patient is dried and allowed to get on the dry side of the bed, and is directed not to rise until the next day. My apology for the sweat is that it always relieves the sore throat, backache, pains in the limbs, and nausea. The relief to the throat from aconite is very great, so much so that the patient can generally take milk with comfort, which he could not do before. The next day there is only slight further treatment for the throat. I generally direct the patient to gargle with hot water; and by hot water I mean *very hot*, as hot as the patient can bear it. Hot water is preferable to cold. There is no treatment before the sweat, and no call for anything further after the gargle. Each time the hot water is used the patient feels better. There is no excuse for carbolic acid or any other medicament. No germicide can be used in sufficient strength to affect bacteria without being injurious to the throat. After the treatment above described there is generally constipation, which is relieved by a seidlitz powder; and I usually prescribe quinine as a tonic, to be taken for some time afterward in small doses.

My reason for introducing the subject of the treatment of follicular tonsillitis is that many physicians do not understand that it is a self-limited disease, and will do very well if let alone. They prescribe some disagreeable or disgusting gargle, which the patient often will not use, and sometimes *cannot*, and which it is practically impossible to employ in the treatment of children, who do not know how to gargle, and who resist anything of a disagreeable nature in the throat.

In a recent number of a Philadelphia medical journal I find an article by a man of that city upon this subject, and I desire to call the attention of the Section to the plan of treatment there advocated. If anything more nonsensical in theory or more disgusting in character can be put together, I do not know what it is. First, the throat is gargled or swabbed with a solution of equal parts of tincture of chloride of iron and water. This is repeated every two hours. The patient is confined to the bed, and not allowed to get up. Ten grains of quinine is given, and repeated in four hours if the fever has not subsided. This treatment is followed up until the throat symptoms disappear, and is then replaced by a tonic. The writer adds, "Cases usually recover in about a fortnight." Think of a child gargling the throat with a fifty per cent. solution of chloride of iron! And the rest of the treatment there advocated is fully as unnecessary as it is painful to the patient and burdensome to the friends. I claim that such treatment is not only useless but unjustifiable in any disease which is bound to get well any way, and which we can influence by measures equally effectual and less troublesome.

Dr. Liebmann observed that in tonsillitis there is according to the books general malaise but no rigor; while in diphtheria there is rigor. It is frequently the case that diphtheria comes on very insidiously, and commences as a tonsillitis, often confined at first to one tonsil, but afterward extending to the other, and being followed by the local signs and constitutional symptoms of usual diphtheria. It is a mistake to suppose that the onset of diphtheria is always announced by a rigor. Tonsillitis may be preceded by a chill, while diphtheria often supervenes without any such symptom.

Dr. Langmaid said: The great interest in follicular tonsillitis consists not in what the disease *is* but in what it is *not*; in other words, in the absence of any exanthem, or parenchymatous disease, or deep-seated infiltration of the throat or other parts, and in the freedom of the patient from any symptoms of a more serious malady. We are never sure that the sore throat, the follicular disease, may not be the local manifestation or the initial symptom of some grave constitutional affection, and we should be ever on our guard

The patient should be watched, and the same precautions observed in mild cases which would be necessary in a far more serious disease. It is not certain that the particular process of sweating has any advantage over the aconite alone or over the old time remedy for sore throat, nitrate of potash. The pain in the muscles is often relieved by the administration of salicylate of soda. All the older authorities speak of colchicum and guiac, and they evidently considered the pains as of rheumatic character.

Given a case such as is described by Dr. Garland, how can the physician be certain that the superficial inflammation is not to be followed by abscess of the parts. Dr. Garland does not probably mean to indicate that *all* cases should be looked upon as absolutely innocent. How can he know that instead of the creamy deposit there may not supervene a thick deposit and all the signs of a grave exudative disease.

Any one who has had the care of diphtheria must feel anxiety upon this point. A subsequent visit should always be made, in order to be certain that no dangerous condition has supervened upon the simple tonsillitis. After the exudation there is sometimes serous infiltration of the tonsil and the symptoms of diphtheritic infection appear.

The observer in Philadelphia is not so far wrong, for he doubtless felt the apprehension of some grave complication, and was striving to ward off more serious evils.

DR. DE BLOIS remarked that there is tonsillitis and *tonsillitis*. In many cases the patient is unable to open the jaws; and when the throat can be examined there may be very little observable change in the tonsil. Scarification of the gland is often a most beneficial mode of treatment.

On motion of Dr. De Blois, it was then voted that the further discussion of this subject be postponed until the next meeting, as an invited guest of the Section who was present had a very interesting case to show to the members.

(To be continued.)

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

JANUARY 14, 1884. DR. CHARLES D. HOMANS, presided.

DR. C. F. FOLSOM reported

TWO CASES OF INJURY TO THE BACK.[1]

DR. J. H. DENNY referred to four cases of injury to the back occurring in his own practice.

The symptoms described in the first case were so largely of subjective origin as to justify the extreme distrust of courts whenever presented as a basis of claim for damages on account of alleged injuries to the back. This is because the same symptoms prevail among girls during the early years of menstruation without previous accident, wherever there is a predisposition toward nervous disorders, which I believe is the chief factor in such cases, however it may be masked.

The second case presents objective symptoms, as anæsthesia, and it is to this class of symptoms, uncomplicated, however, with mental phenomena, that I wish to allude, as illustrated in several cases observed by myself at the department for nervous diseases in the City Hospital, showing that seemingly even slight injury, if real, is followed by pronounced objective symptoms. In none of these cases was there history of syphilis or any other predisposing cause.

(1.) A robust laborer was suddenly fastened, by a caving of stones and earth, below the last dorsal vertebra. When released he could walk home, and was not confined to bed, nor did he suffer pain to any great degree. After the lapse of six months I found him with the following symptoms: Legs weak, slightly anæsthetic, gait broadened and stiff, marked ankle clonus, and exaggerated patella reflexes. The symptoms were in brief those of lateral sclerosis, with probable extension of the process to the posterior segments of the cord. The patient remained otherwise in excellent health.

(2.) Following injury to the lower dorsal region in a laborer I found, several months subsequently, marked exaggeration of all the tendon reflex phenomena, occasional spastic rigidity of legs, cutaneous hyperæsthesia, paraplegia, and paralysis of the bladder. These symptoms indicated a symmetrical sclerosis, as in the preceding instance.

(3.) A healthy woman was thrown from a horse, but not immediately disabled. Her legs gradually lost strength, and became more or less anæsthetic, while the symptoms of ankle clonus and highly exaggerated patella reflex phenomena were likewise slowly developed. About a year afterwards, when seen by myself, she was unable to walk, but otherwise in excellent health and spirits.

In such cases degeneration of the lateral and posterior columns appears to have occurred, beginning below and progressing in the form of an ascending sclerosis, affecting the lower limbs first.

In the reported cases of ordinary forms of such disease, not resulting from similar injury, the process begins above, and is a descending sclerosis, affecting the upper extremities first.

In four cases of injury to the back below the dorsal region, reported by Dr. Schultze,[2] of Heidelberg, an ascending degeneration, affecting the lateral and posterior segments of the cord, was found on post-mortem examination. As yet such records of traumatic ascending sclerosis are very rare, but the plain evidence of the clinical modifications of motion and sensation in these cases of injury to the back indicates a similar pathological explanation.

DR. J. J. PUTNAM said that he had seen various manifestations in the same general train of hysterical symptoms occuring in these cases. Robust men, as well as women, may have typical hysterical hemianæsthesia, the symptom being mainly cerebral and not spinal. He also said that one should guard against mistaking a sprain of the deep muscles of the back for concussion of the spine, a condition which, in his opinion, has no existence. He thought, with Dr. Folsom, that rest is very necessary in the early treatment, but that it need not be continued indefinitely.

THE PRESIDENT reported

A CASE OF CHRONIC ULCER OF THE DUODENUM.

The patient was a physician, aged fifty-seven years. In early life he had always enjoyed excellent health,

[1] See page 97 of this number of the JOURNAL.

[2] Archiv f. Psych., etc., Bd. xiv., 1883.

never having been confined to his chamber but for a few days. He was quite robust and fond of out-door exercise, particularly of walking. He had lived a very regular life.

About nine years ago he began to complain of pain in the epigastrium, which he regarded as gastralgia, at times attended with nausea, though not then enough to keep him from his work. This pain was not aggravated by eating, but on the contrary was frequently assuaged by a meal. It was paroxysmal in character, and frequently quite severe, though not at that time necessitating the use of opiates.

In 1878 he went abroad, and while there seemed to recover entirely; the pain left him, and he seemed as well as ever. On the passage home he had again great nausea attended with vomiting, and arrived in Boston in quite a miserable condition. He gradually improved and attended to his business, though having at times more or less pain.

In 1879, while at Bar Harbor for his summer vacation, he suffered during a great part of the time from nausea and pain, at times so great as to confine him to the house and even to his bed; then these symptoms would subside, and he was able to take long walks with satisfaction. After his return home he became better, and was able to do his duty as physician and professor through the winter.

In the last days of May, 1880, he had several large hæmorrhages from the bowels which weakened him very much. He was confined to his bed and chamber for several weeks, but at the end of June was able to go to Bar Harbor, where he passed the summer. He gradually regained strength enough to take short drives and moderate exercise. His urine at this time contained a great deal of uric acid, and in November, after several days of pain, necessitating the use of morphine and ether, he passed a small renal calculus.

Through the winter of 1880–1881 he had attacks of pain, sometimes with and sometimes without nausea, but he was out a great portion of the time, attending to his professson in part.

The summer of 1881 was again passed at Mount Desert, but his sufferings were greater than they had ever been. He was almost continually nauseated, vomited a great deal, and, as he said, "in agony" unless when under the influence of morphine or ether. He became very much emaciated, and came home in September much worse than in the spring. The matter vomited consisted usually of thick mucus, and was very acid. He gradually improved, and during the winter could drive and walk about for short distances, and at times see patients, frequently, however, being troubled with pain and obliged to pass more or less time in his chamber.

The summer of 1882 was much more comfortably passed. He returned to the city, and during the winter was just about as well as the year before.

In May, 1883, he was in his bed for about three weeks with pain, nausea, and vomiting, but was able to go to his island home in the early part of June. Here he immediately began to gain flesh and strength, and for about three weeks had but little pain and enjoyed himself very much. But the old symptoms returned, and he spent a great portion of the summer in his chamber. He came back to Boston in September, and during the fall took short drives and walks, having, however, more or less pain every day. On November 12th he had a severe attack of pain and vomiting during which some altered blood was thrown up. From this time till his death his time was principally passed in his chamber, but in the intervals of comparative ease he went down stairs and out of doors several times. In the night of December 12th–13th he seemed in great agony, and ether was inhaled early in the morning with relief. At this time some tenderness was found at the right of the middle of the epigastrium, which gradually increased and was attended with some swelling, and it was evident that peritonitis was present, probably owing to perforation. He died at half-past six P. M. December 14th.

When the attacks of pain first came on the patient regarded his disease as gastralgia. Afterwards there was a question of malignant disease, but the long duration of the symptoms without the development of a tumor seemed to militate against that theory. As there was never any tenderness of the abdomen in any part, and as the pain was usually mitigated and frequently entirely relieved by the use of food, the diagnosis of chronic ulcer was for a long time uncertain, but after the hæmorrhages from the bowels, of which there were several slight ones besides the severe attack mentioned above, it was considered that his symptoms could be accounted for in no other way than by an ulceration of the duodenum, probably very near the stomach.

By way of treatment all the drugs usually employed to assist digestion were used without any good result. He declined to try the benefit of complete rest and a very restricted diet. Vegetables, sugar, and ordinary bread were not eaten, but when well enough he partook of everything else, though never with any great appetite. Milk and Mellin's food he could take when he could bear nothing else, and he always had one or both of these articles with him even when he went on a short drive. The pain was kept under by the subcutaneous injection of morphine, which he gave himself in the epigastrium. The amount used varied very much. For the last few weeks of his life he never used less than a grain and a half, while sometimes he would inject four grains in the course of twenty-four hours. As might be expected, constipation was a constant symptom. Recourse was had to the inhalation of ether when the pain came on very suddenly and severely, but it was little used save during the summer of 1881, and during the last thirty-six hours of life. He bore his sufferings very bravely, and as soon as the pain was relieved in some degree he would take up his work on a book, which he did not live to finish. He showed great self-control by always reducing the dose of morphine the moment it ceased to be necessary to alleviate his discomfort.

He was seen during the course of his long illness by Drs. Morrill Wyman and Francis Minot in Boston, by Drs. Longstreth and Amory in Bar Harbor, and at several emergencies by Drs. Cutler and Garland, whose devoted care he highly appreciated.

Dr. E. G. Cutler said that on opening the body there was general peritonitis, with little effusion, due to perforation which had taken place in the duodenum. On opening the duodenum one open, and one partially or wholly cicatrized ulcer was found. The former was just without the pylorus, and was the one where perforation had occurred, and the latter was an inch or more beyond it. Each was nearly the size of a quarter of a dollar, with abrupt edges. There were no enlarged glands, and nothing suggestive of a cancerous

nature was found. The source of the hæmorrhage was not seen on a superficial examination. At the apex of each lung there was some thickening of the pleura with condensed lung tissue underneath, and increase of the interlobular connective tissue of about an inch and a half area. A minute calculus was found in the pelvis of one kidney, and there was slight pyelitis of the organ. The organs, aside from presenting an anæmic appearance, were healthy.

DR. R. H. FITZ recalled the case of a man of sixty with ulcer of the duodenum, who had slight pain after eating, but no other symptom until perforation occurred.

DR. W. W. GANNETT thought that more blood had been lost than was at once apparent, as the fæces were stained with altered blood pigment, although there were no corpuscles. This pointed to small hæmorrhages.

DR. FITZ remarked on the value of an analysis of diets.

DR. HOMANS had never seen much difference in this patient in that regard.

DR. A. T. CABOT presented a specimen of Osteo-Sarcoma of the Head of the Femur, of five months' duration, from a boy of seventeen.

DR. W. G. WHEELER showed a specimen of

MALIGNANT DISEASE OF THE KIDNEY,

occurring in a man sixty-two years of age. Ascites existed, and the tumor was not detected until the patient was tapped, when sixteen pounds were removed, and a nodulated swelling was discovered. The urine was normal until four weeks ago, when blood appeared. There were neither vomiting nor pain, and the man had been at work until October, although he was treated elsewhere in June for disease of the liver. Œdema made its appearance first in one and then in the other leg.

DR. FITZ spoke of the rarity of the disease, there having been three or four specimens shown in this Society in three or four years, and they coming, some of them, from a distance. These cases are especially rare in children, but they do occur.

DR. WHEELER remembered a similar case in a child of five.

DR. GANNETT mentioned three cases, of from five to fifteen years, in Bamberger's clinic while he was in Vienna.

DR. H. K. SABINE said that in seven cases in children, reported by Monti, bloody urine was seen in two.

NEW YORK ACADEMY OF MEDICINE.

ANTISEPTICS IN THE NEW YORK HOSPITAL.

AT a meeting of the Academy of Medicine, held January 17th, DR. R. F. WEIR delivered an address entitled How Antiseptics are Used in the New York Hospital, — A Demonstration. In speaking of various antiseptics he said that carbolic acid and iodoform were open to serious objection on account of the dangers attending their use from poisoning. In the substitution of bichloride of mercury for such agents a great advance had been made. He had first employed the bichloride as an antiseptic in March, 1882. It was after reading the paper of Delacroix, and he used it at first in a very imperfect way. Since the publication of the researches of Koch, Kimmel, and others, however, we now had very clear ideas on the subject. It had seemed to him the acme of an antiseptic for surgical purposes, efficient, safe, and cheap, but during the last few days he had discovered that it was not entirely free from objection, since its solution was not durable. In the course of one or two weeks it became changed to calomel, as he had found by testing surgical dressings saturated with it with lime water. A few days since he had written to Professor Gibbs, of Harvard, in regard to the matter, and he had just received a letter in reply from him, in which he said that he thought the solution of bichloride might be made durable by the addition to it of a small quantity of common salt, say five parts to one thousand. He proposed, however, to make some further investigations on the subject.

In the New York Hospital wounds were generally dressed with gauze or cheese cloth impregnated with a solution of the bichloride, and a special gauze, free from sizing (which consisted of oily material), was manufactured for the hospital, which cost four cents a yard. The sizing could be removed from gauze which had it, however, by washing it with weak muriatic acid. The solution of the bichloride usually employed was made up as follows: bichloride of mercury 20 parts, water 44,480 parts, glycerine 500 parts. It was sometimes used as strong as one to 1000. The glycerine was added to prevent the gauze from entirely drying, as it became a little weakened when quite dry. Dr. Weir then exhibited a number of other substances which were employed for surgical dressings, such as cotton, jute, peat, wood-pulp, and moss. Of these peat was the most absorbent, taking up sixteen and a half times its weight of water, and it was also the cheapest, with the exception of the moss, costing six cents a pound. That which was used was of two varieties, the light and the dark colored (the two being sometimes mixed together), and it was imported from the north of Germany, though he had no doubt that it could readily be obtained in this country. The dressing which he preferred to all others was jute. This was bleached, pressed, and finely carded, and differed very greatly from the article with which most were familiar under this name. It seemed to him the ideal surgical dressing, although it was more expensive than the other substances named. Moss cost almost nothing, and in the few cases in which he had employed it it seemed to answer very well.

If an amputation, for instance, was to be performed, it was his practice to wash the part the day previous, or on the morning of the operation, with a mixture composed of two ounces of turpentine to a pint of alcohol. Before commencing the operation the "protector" was placed on the patient. This was simply a rubber cloth, with a hole through which the limb to be amputated was slipped, to keep the rest of the body dry. He had seen it used in the German hospitals during a recent trip abroad, and there it was a necessity, as antiseptic fluid was used very freely to irrigate the parts all through the operation. In regard to the spray, he said that personally he had abandoned its use except in operations about the joints and the abdominal and thoracic cavities, in which he still retained it. At this point he mentioned that Esmarch had devised some "antiseptic knives," in which the blades and handles were made of a single piece of steel, so that septic germs could not possibly lodge about them. The objection to them was that if the handles

became bloody they were very slippery, and so Tieman, of New York, had made a modification by constructing the handle of baked rubber, but entirely free from crevices.

Having exhibited a number of the most recently invented hæmostatic forceps, the most admirable of which he considered the instrument of Hahn, of Berlin, he returned to the consideration of the supposed operation. The amputation having been duly performed, and any hæmorrhage that might have occurred arrested as promptly as possible, the vessels were tied with catgut ligatures. Formerly he had always used Lister's carbolized ligature, which was quite strong, but objectionable on account of its slipperiness, from the fact that it was prepared with a solution of carbolic acid in oil. Moreover, Koch had recently found that carbolic acid when mixed with olive oil altogether lost its antiseptic properties. Lister had also recommended a ligature prepared with chromic acid; but the objection to this was that it lasted too long, and, consequently, acted as a foreign substance in the tissues, and was liable to cause more or less irritation. The ligature which Dr. Weir now used was one composed of fine catgut treated with solution of bichloride of mercury. It was prepared by dipping it first into a solution of the strength of one to one hundred for ten minutes, and then leaving it immersed in a solution of one to one thousand for twelve hours, after which it was wound on a bobbin and put into ninety-five per cent. alcohol. A ligature thus prepared was liable to be somewhat brittle, but this difficulty could be avoided by mixing oil of juniper with the alcohol. It would be even better, he thought, if it was kept in pure oil of juniper.

The wound was closed with the continued instead of the interrupted suture, catgut ligatures being used for the purpose, and openings being left at both ends for the insertion of drainage tubes. The black rubber tube was that usually employed, but one trouble with it was that if it was allowed to remain in position for more than from three to five days an open tract would be formed which would remain too long. If, on the other hand, the tube were withdrawn earlier than that it would necessitate the changing of the entire dressing, which was often a great disadvantage. In order to obviate this difficulty a decalcified bone tube had been devised, which after a time became entirely dissolved. After the drainage tubes had been placed in position the whole wound was flushed with bichloride of mercury solution until the latter came away perfectly clear. Compresses of antiseptic gauze were then fastened over the wound with sufficient tightness to keep up a moderate amount of pressure, and over these was placed the absorbent cushion, made of one of the substances before mentioned tacked in, so that it would not become disarranged. Then over the whole dressing a crinoline bandage was applied. In many instances an amputation was expected to heal under one or two dressings, and it was found, as a rule, that the fewer the changes of these the more rapid the progress towards cure.

All this, of course, presupposed cleanliness, and, indeed, some went so far as to say that the entire secret of the success of antiseptic methods depended on this point. Lawson Tait, of Birmingham, who did not practice Listerism, and yet had achieved such wonderful success, was the apostle of cleanliness, and his operating room, Dr. Weir said, was the cleanest place that he had ever seen. All his instruments were kept under water, and he was particularly struck with the care which he observed in preparing his sponges. When visiting his wards he saw quite a number of cases of ovariotomy, hysterectomy, and other serious operations, and all were doing well. The only trouble that he noticed was two or three stitch-hole abscesses, which he thought would not have existed if antiseptics had been used. Keith, of Edinburgh, practiced the antiseptic method, with the exception of the spray, which he rejected. Some surgeons now, during their operations, in lieu of using the spray, kept the parts wet with a boro-salicylic acid solution.

Dr. Weir thought it was a point of great importance to use extreme care with the sponges employed in surgical operations, as he believed that more risks were run in this direction than in almost any other. Sponges could now be purchased so cheaply that he thought it advisable, as a rule, to throw them away after using them once. The sponges which were employed at the New York Hospital were first thoroughly hammered, in order to get all the sand out of them, and then placed in warm water, which was preferable to hot. Next they were kept in a solution of permanganate of potassium for about twenty-four hours, and then washed out in water, after which they were treated with a solution of one part of sulphide of sodium to one hundred parts of water, to which had been added one fifth part of a solution of hydrochloric acid or oxalic acid (one to one hundred). Next they were placed in running water, and finally dipped in carbolic acid solution, one to twenty, or bichloride of mercury, one to one thousand. If used in operations about the vagina, rectum, or abdomen, the sponges were thrown away after being used once, but after being used in amputations and other operations they were cleansed and disinfected by the same process by which they were originally prepared.

In concluding, Dr. Weir gave some statistics in regard to compound fractures and amputations, which showed in a very striking way the advantages of the antiseptic method. In compound fractures the rate of mortality at St. Luke's and the Roosevelt Hospitals, New York, had formerly been thirty-three per cent. In the old New York Hospital it had been sixty per cent., and in the Boston City Hospital forty-one per cent. With the open method it had been twenty-six per cent. Under the strict antiseptic plan, however, the mortality in compound fractures in Dr. Weir's hands had been only six per cent., and some surgeons had reported even a better showing than this. On account of the saving of life secured by the methods which he was the first to propose he thought, therefore, that the name of Joseph Lister was entitled to more honor than any other in this century, not excepting that of the discoverer of anæsthetics.

THE NEW YORK COUNTY MEDICAL ASSOCIATION.

DR. AUSTIN FLINT ON THE PATHOLOGICAL AND PRACTICAL RELATIONS OF THE DOCTRINE OF THE BACILLUS TUBERCULOSIS. — PRESENTATION OF A SPECIMEN OF HYDATID TUMOR OF THE SPLEEN.

The first public meeting of this new Society, which has been organized for the purpose of upholding the National Code of Medical Ethics, and securing the representation of the profession of New York again in

the American Medical Association, was held at the College of Physicians and Surgeons, New York, on the 14th of January. The president of the Association is Dr. William Detmold, the vice-president, Dr. Charles A. Leale, and the secretary, Dr. E. A. Judson. It was a large and enthusiastic gathering, and when, after a brief inaugural address by the President, Professor Flint arose to read his paper on the Pathological and Practical Relations of the Bacillus Tuberculosis he was received with a prolonged storm of applause. Before commencing it he congratulated the Society on the auspicious circumstances under which it had started upon its career of usefulness, and said that he esteemed it no small honor to be the first to present a scientific communication to it.

The history of tuberculosis during the last quarter of a century, he said in his paper, afforded a striking example of the mutability of medical opinion. About twenty-five years ago Virchow had enunciated the doctrine that the term tubercle should be confined exclusively to the so-called granulations of Bayle. This dogma, which was founded upon a pathological basis, was universally accepted, and from this time phthisis and tuberculosis were regarded as entirely distinct diseases, although it was admitted that the two were associated in certain instances. This view, however, was in direct opposition to the results of the clinical studies of such masters as Laennec and Louis, and so in order to reconcile the old opinions as far as possible with the new, certain predisposing and concomitant conditions were classed under the term vulnerability. The therapeutical aspects of Virchow's doctrine were unfortunate, for patients affected with phthisis were subjected to measures designed for the treatment of chronic inflammation, such as local blood-letting, mercurials, and confinement within doors, notwithstanding the fact that this course was opposed to the clinical results of the illustrious teachers mentioned.

It had required nearly a quarter of a century to convince the profession that these views, based on the microscopic investigations of Virchow, were erroneous, and the conclusions to which they led false. This whole matter, therefore, taught the evil of rash deductions from pathological research, and not only this but the safety of trusting to clinical experience. The lessons taught by Laennec, Louis, and the other great clinical lights of their school were as valuable to-day as they ever were.

Dr. Flint then went on to speak of the researches of Villemin, who, in 1865, announced the inoculability of phthisis. That there was a specific virus, however, was generally regarded as disproved by the fact that the inoculation of other agents beside tubercle seemed also to induce tuberculosis in certain animals. This apparently fatal objection was in a great measure entirely removed when Koch made known his discovery of a specific organism characteristic of tuberculosis in the year 1882. Two things were remarkable about this discovery: (1) that it should at once have excited so much interest in all parts of the civilized world, and (2) that the bacillus tuberculosis should be so generally accepted by practical histologists, who were most competent to disprove or confirm its existence and significance. Having stated that positive proof of the bacillus being a micro-organism distinctly characteristic of tubercle had been afforded by the results of its culture under circumstances which excluded all sources of error, Dr. Flint next proceeded to inquire into the nature and extent of its connection with tubercular disease. The all-important question was whether or not it was the causative agent, and the experiments in the cultivation of the bacillus, quite devoid of any morbific agent adherent to it, outside of the body, he thought had demonstrated conclusively that the question must be answered in the affirmative. Koch's observations had never been successfully disproved. It followed that pulmonary phthisis was an infectious disease, a multiplication of the causative agent taking place within the body. Two conclusions could, therefore, now be stated: (1) that no case of phthisis took place without the presence of the bacillus, and (2) that phthisis was primarily a local disease, having its seat in the lungs, and directly due to the agency of the bacillus. The local pathological process extended, and the development of the disease in other parts of the system depended on the migration of bacilli.

He next took into consideration certain clinical facts which seemed to bear against Koch's hypothesis. This antagonism, he thought, was apparent rather than real. Pulmonary phthisis was undoubtedly a diathetic disease, and heredity was not merely an accidental coincidence in connection with it. In some climates the disease was met with more frequently than in others, and a humid soil, defective alimentation, mental depression, want of ventilation, confinement within doors, and similar conditions were believed to have no little to do with its causation. Age also was a point that entered largely into its ætiology. How could these facts be reconciled with the proposition that the efficient cause was a *contagium vivum?* In order that this contagium should produce its effect upon the system certain special concurrent and coöperative requirements were necessary. The nature of these conditions was unknown, but the fact of their essential importance was perfectly certain. They might all be embraced under the name *predispositions.* The same elements of a contagion and a predisposition were very evident in yellow fever, for instance, and in this disease the two had been very aptly compared by the late Dr. Barton to the two blades of a pair of scissors, which were only of use when coupled together. The contagium and the predisposition were perfectly inert unless combined with each other. The predisposition in phthisis was the diathesis, and this might be either congenital or acquired. It was practically impossible to avoid the inhalation of bacilli as long as phthisis was as common as it was at present almost everywhere in the world, and in the consideration of this affection it was necessary to apply to it the same truths that were applicable to other infectious diseases.

Proceeding to consider the matter of diagnosis, he said that of its great importance he was able to speak from a very considerable experience. Not professing to be himself a skilled microscopist, he had had the sputa of a large number of patients suffering from phthisis examined by Prof. William H. Welch and other competent observers, and the bacillus had always been found to be present. In any case where there had previously been any doubt about the diagnosis, if the bacillus was discovered it was regarded as proof positive of the existence of phthisis. If it was not found the presence of the disease might be doubted. He thought, therefore, that the time was not distant when the examination of the sputa in thoracic affections would be as common as that of the urine in suspected renal disease. So far as his experience went

the abundance or fewness of the bacilli found in any instance was a sure index of the activity of the tubercular disease present, and this was a point which had an important bearing on prognosis. For a long time past, Dr. Flint said, he had taught that phthisis was a self-limited disease, and the explanation of this he now believed to be that the race of bacilli after a time became extinct.

The next point taken up was the prevention and treatment of the disease in their relations to the bacillus. In order to insure protection against it it would be necessary (1) to avoid all exposure to contagion, and (2) to remove all predisposing causes. The first point it was evidently impossible to carry out unless we could find some spot in the world where there had never been a case of phthisis. Even at this moment the gentlemen present might be inhaling bacilli if there were in the room any individual suffering from the disease. Perhaps as safe a place as could be found was on shipboard, provided no case of phthisis were on the vessel; but it would not do to order perfectly healthy persons to spend their lives at sea. The danger from exposure varied in proportion to its degree and extent; and here a great deal could be gained. Healthy individuals should breathe as little as possible the same air as those suffering from phthisis, and the disinfection of the sputa of such patients should not be neglected. The freest possible ventilation should also be insisted upon; and not a little might be gained by attention to such points as these. In the removal of predispositions we had to contend with the difficulty of recognizing the presence of the predisposition before it was too late. If deaths from phthisis had occurred in the family, however, the predisposition certainly existed, and special care was to be enjoined during the early years of the individual. If the existence of any predisposition was simply probable, it was better to err on the side of over-caution, and the lessons of common sense and experience would offer a safe guide. Residence in a dry, salubrious climate with an atmosphere rarefied by elevation, the maintenance of cheerful spirits, exercise in the open air, and the highest grade of constitutional vigor attainable had been shown to be useful preventive agents.

Theoretically the treatment would consist of (1) the destruction of the parasite, and (2) the removal of conditions under which it thrives. Although not two years had elapsed since Koch's discovery was announced to the world, a large number of agents had been proposed and experimented upon with a view of destroying the bacillus, such as corrosive sublimate, iodoform, arseniate of soda, and salicylate of soda. As yet no efficient parasiticide had been found which, when taken into the system in sufficient quantity to have any effect upon the bacilli, would not prove injurious to the patient; but that this end might be achieved in the future was not beyond the range of possibility. The removal of the conditions upon which the existence of the parasite depended could be carried out better. The disease would cease to exist when the two factors, the bacillus and the predisposition, could be done away with. The discovery of Koch, therefore, while it had thrown much light on the ætiology and pathology of phthisis, as well as given us considerable aid in the way of diagnosis and prophylaxis, had not materially affected the treatment of the disease, in which we must continue to trust to the light of reason and experience.

DRS. WILLIAM H. WELCH, E. G. JANEWAY, and GEORGE PEABODY all stated that they were in complete accord with the views advanced in the paper, and also spoke of the comparatively little value of negative testimony, especially after a single examination, in regard to the bacillus as compared with positive. Dr. Janeway called attention to the fact that in the early stages of the disease it was often difficult to obtain any sputa at all from patients. In some instances in which this had been the case he had found later on in the course of the disease that bacilli were abundant in the sputa.

The discussion was brought to a close by DRS. LEALE and NELSON, who related cases in which tuberculosis seemed to be directly communicated from one member of a family to others. In that given by Dr. Leale a family of six individuals was entirely swept away by the disease within a space of ten years.

DR. WILLIAM H. WELCH then presented a specimen of hydatid tumor of the spleen, which had been removed from the body of a German who died in Bellevue Hospital from extensive superficial burns; there being no previous history of disease. The tumor was a large echinococcus cyst with a firm fibrous capsule, and also characterized by some calcareous deposits. On making an incision into it about four ounces of opalescent fluid escaped, and within it was a large mother cyst, which had collapsed. About this were at least two hundred daughter cysts, varying from the size of a pea to that of a hen's egg. The growth was, therefore, of the exogenous variety, which was stated to be considerably more rare than the endogenous, in which the daughter cysts are formed within the mother cyst. No heads of echinococci were found, but some hooklets were met with. Dr. Welch then proceeded to give a demonstration on the blackboard of the development of echinococcus cysts in the human subject, and in conclusion spoke of the third variety, the multilocular, which, he said, had never been met with in this country, and which, as it was found exclusively in Switzerland and Southern Germany, he thought was probably not produced by the same embryo as the exogenous and endogenous cysts.

NEW YORK NEUROLOGICAL SOCIETY.

STATED meeting, January 8, 1884.

DR. WILLIAM J. MORTON, President, in the chair.

NOTE ON THE USE OF THE MENTHOL CONE AS AN ANODYNE.

DR. E. C. WENDT showed a little contrivance called by the Germans "*Migräne Stift*," and explained its application and uses. It consisted of a piece of menthol moulded into a conical shape and secured in a little wooden box, closed by a cover to prevent evaporation and breaking. It seemed to be little known here, although it was much used abroad, especially for sick headache.

His attention had been first directed to the anodyne properties of menthol by a short notice in the *Medical Record* of April 28, 1883, by Dr. Cammann, who had recommended an alcoholic solution of menthol (one drachm to one half ounce alcohol) to be painted over the affected parts. Dr. Wendt had since that time often used this solution, and found it an anodyne.

In this country menthol had not yet received that amount of recognition from the profession to which

its pain-obtunding properties would seem to entitle it. In fact, little seemed to be known about it, and for this reason Dr. Wendt thought it might not be amiss to quote a descriptive notice of it: "Menthol, or menthylic alcohol, is a crystalline substance, deposited from the oil of peppermint, prepared in China and Japan from *Mentha Arvensis var.-piperascens* and *glabrata*." It formed the chief ingredient of a much valued remedy for neuralgia before its source was generally known, what was sold in small bottles, labeled with Chinese characters.

It is a white crystalline stearopteno, melting when pure at 97° Fahrenheit, and is obtained by the Japanese from the oil of peppermint by submitting it to freezing several times in succession until no more menthol crystallizes out.

It is also said to be contained in the American and English oils of peppermint, but probably in small quantities only. It is somewhat surprising that the Japanese peppermint plant which is grown in England as a curiosity has not been cultivated in that country, as a source of the drug, the supply of menthol being uncertain, the demand great, and the price in consequence occasionally very high.

Menthol is said to be sometimes adulterated with crystals of Epsom salts, to which it bears a great resemblance. These being insoluble in alcohol or chloroform, in which fluid menthol is freely soluble, can easily be detected. Samples of fine crystals sometimes contain some essential oil adhering to them, a fact which must be taken into consideration when the menthol is made into cones or pencils.

Menthol is but slightly soluble in water, although imparting a strong odor and taste to that liquid, and is soluble in aqueous alkalies. It is soluble in fixed and volatile oils and in ether.

Although Dr. Wendt's experience with menthol had not yet been a very extended one, it had nevertheless been sufficient to convince him of the utility of the drug in a rather large class of cases. He had found it a pleasant and reliable anodyne in all the lesser neuralgias, and especially in those so frequently occurring about the face, but it was also serviceable in many painful affections due to inflammatory processes. Its topical action was similar to that of aconite, over which it had the advantage of not being poisonous.

Dr. Wendt remembered one rather striking case of quite severe supra-orbital neuralgia, which refused to yield to the oleate of aconitia, but was much benefited by menthol. But, on the whole, in violent attacks he had found it almost useless. In typical migraine, for instance, where the pain was at all severe, and in all deep-seated aches of more than very moderate intensity, it had no appreciable effect, except, perhaps, the indirect psychical action of distracting the sufferer's attention.

In the discussion which followed these remarks, DR. ROBERTS asked Dr. Wendt if he had tried the prolonged application of menthol.

DR. WENDT said that he had in some cases of hemicrania, though without decided benefit. Nevertheless, the patients experienced a pleasant sensation of coolness of the surface, followed by a feeling of agreeable warmth.

DR. MORTON thought that menthol probably acted more after the manner of counter-irritants, by insuring relief in a reflex rather than in a directly local way. Mustard was a typical peripheral nerve-irritant, and it seemed to him that the action of menthol could be best explained on the same principle of procuring peripheral nerve-impressions in a reflex way. Dr. Morton's attention had been first called to the menthol-cone by Dr. Wendt. He chanced to be at the latter's office one day when suffering from a headache. A few strokes of the menthol gave him at once a sense of relief. He felt the effects of the peppermint to be as gratefully cooling as the application of cold metal. In brachial neuralgia, as well as in sciatica, he had been pleased with the good effects of menthol. He thought the drug was deserving of further trials.

DR. RALPH L. PARSONS then read a paper on

DETENTION IN ASYLUMS.

The reader considered the questions whether sane persons were not often unjustly detained in asylums for the insane; and, secondly, whether many uncured and incurable patients were not methodically detained in asylums who might advantageously be returned to their relatives, or placed in the care of private families under State supervision.

It was assumed in the first instance that the detention of patients after recovery had taken place was quite possible and even probable in some instances, but that such detentions were not usually of serious import to the patient; that, on the other hand, too early discharge might be more injurious. It was also admitted that maliciously unjustifiable detentions were possible, as any other sort of injustice is possible on the part of persons holding positions of power and responsibility. But reasons were urged in support of the belief that such malicious detentions were at least very rare; that sentiments of honor and professional pride were strong deterrents, to say nothing of the great danger of detection in the commission of the wrong, and the ease with which patients who were decidedly insane obtained their enlogement through the intervention of the courts.

Cogent reasons were given why various classes of convalescents ought to remain under asylum care for a period of time after they appeared to be well; as, for instance, when they would be immediately subjected to the exciting cause of their insanity on their return, when the progress toward convalescence had been characterized by relapses, or when dangerous delusions had been entertained and had faded away so gradually that there were difficulties in judging whether they had passed away entirely.

But, on the other hand, the discharge of certain uncured curables before they were well was advised, as when after making a certain degree of improvement, this improvement stopped, and the patient seemed to retrograde. It might be highly advisable to discharge some of these patients before they were well.

The major part of the paper was devoted, however, to an advocacy of the discharge from the asylum of harmless incurables and their return to the care of their friends, or placing them with ordinary families as boarders. However comfortable and happy such patients may appear to be in large asylums, there are many causes of discomfort that would not be experienced in ordinary family life. Quotations were made from Dr. Bucknill and from Dr. Maudsley strongly supporting these views.

The question was then considered, what classes of incurables might safely and with benefit be released from asylum restraints. Since in the case of a great

majority of such patients moderate cost of maintenance would be essential, those only would be adopted who were quiet and orderly, and would require no especial supervision. Habits of industry would be favorable.

Whether such patients would do better with their relatives or with strangers would depend on the circumstances of the family, the feelings or notions of the patients, etc. Many patients who would not do well with their own kindred would be happy and useful with congenial strangers. It would be impossible for the patient to resume his former position and influence in his own family, and hence he would be subjected to annoyance there.

As a preliminary measure, a system of legalized furloughs was advocated, to the end that at first the patient might still be under legal restrictions and easily returned to the asylum if the trial at large should prove a failure.

The paper closed with the following summary of conclusions, to wit: —

(1.) That, inasmuch as many recoveries take place in asylums for the insane, it is to be expected that some convalescent patients may at any time be found in the wards.

(2.) That while possibly now and then a convalescent patient may be detained on probation an unnecessary period of time, such cases are not of frequent occurrence, nor important in their consequences when they happen, and that when they do occur the detention is very rarely indeed through criminal intent.

(3.) That many harmless incurables are unnecessarily detained in asylums for the insane; that these incurables would be happier in the enjoyment of ordinary family life and associations, and that systematic efforts should be made to secure their enlargement and their establishment under family care.

(4.) That under certain circumstances curable patients should be removed from asylum restraint and associations while yet uncured.

Owing to the lateness of the hour, the discussion upon Dr. Parsons's paper was postponed until the next meeting of the Society.

Recent Literature.

Transactions of the American Gynæcological Society, Vol. 7, 1882. H. C. Lea's Son & Co.

Full abstracts of the papers read at the meeting of which this volume is the official report were widely published in the weekly journals; but so long a time has since elapsed that the book has almost the charm of novelty. We learn, however, that the Transactions for 1883 are already in press, and that hereafter the successive volumes will be promptly issued.

The President, Dr. T. A. Emmet, departing from the custom of his immediate predecessors, chose a professional subject as the topic for his annual address; namely, A New Method of Exploration, with the Pathology and Treatment of Certain Lesions of the Female Urethra. The new method consists in making a button-hole-like opening into the urethra, avoiding the urethral outlet and the neck of the bladder: through this opening ocular and digital examination can be made, and appropriate treatment effectively applied. The urethral fistula thus created can be kept open a longer or shorter time, as required for purposes of treatment, and then closed like a vesico-vaginal fistula, except that the sutures must be passed so as to include the urethral mucous membrane. This method has borne the test of experience, and seems to us to be a great advance in operative gynæcology. Dr. W. H. Baker's communication showing the value of bladder drainage by cysto-vaginal fistula in the treatment of hyperæmia of the neck of the bladder is of especial interest in this connection.

Dr. J. T. Johnson's paper on the Proper Use of Ergot in Obstetrics emphasizes the well-known dangers of this drug, if given before the uterus is empty. We quite agree with Dr. Johnson that, viewing the use of ergot as a whole, the race would be better off without it altogether: and we believe with him that midwives, in whose hands this drug becomes in many cases a veritable "pulvis ad mortem," should be restrained, by legislative means if necessary, from its indiscriminative use.

Dr. Fordyce Barker's paper reminds the profession that leucorrhœa is not a disease to be treated as such, nor the symptom solely of uterine disease, but is often the expression of a constitutional cause which should be combated by appropriate general and hygienic treatment. The tendency of many gynæcologists is to lose sight of this fact in their zealous administration of local treatment.

The valuable paper of Mr. Knowsley Thornton shows by the careful comparison of statistics that the complete removal of the uterine appendages is a safer operation than supra-vaginal hysterectomy, and, at the same time, an equally effective procedure for the cure of uterine fibroids. There are cases, of course, where the latter operation must of necessity be performed, but the mortality reaches the high figure of from thirty to forty per cent. even in the hands of experienced surgeons. On the other hand the experience and intelligent observation of Mr. Thornton have convinced him that the milder operation cures the disease, and that the mortality therefrom should be *nil*. It is necessary however, for success, not only that the ovaries should be completely removed, but that all the lateral vessels in the broad ligaments should be completely ligated and the chief blood supply to the uterus thereby cut off. The paper is an admirable exposition of the present status of the two operations.

Dr. Van De Warker's exhaustive paper on Mechanical Therapeutics of Versions and Flexions of the Uterus deserves careful study by all who resort to mechanical means for the correction of uterine malpositions. The profuse illustrations add greatly to the value of the communication.

Dr. J. Collins Warren submits a new method of operative relief in certain cases of complete rupture of the perinæum where the recto-vaginal septum is largely involved. This method is now undergoing the test of experience, and, so far as we learn, with gratifying results.

The contribution of Dr. M. D. Mann concerning Surgical Operations on the Pelvic Organs of Pregnant Women collates the experience of many eminent gynæcologists and throws much light on a subject on which it was much needed. The paper will repay careful study.

Dr. W. L. Richardson presents a fourth and fifth series, of one hundred and eight cases each, of measurements of the uterine cavity in childbed. This brings the number of cases reported by Dr. Sinclair and himself to five hundred and forty; and when the number

reaches one thousand it is Dr. Richardson's purpose to present general deductions therefrom: the profession will await the final report with interest.

The remaining papers are by Dr. Thomas on the History of Twenty-one Cases of Extra-uterine Pregnancy; Dr. Garrigues on Electricity in Extra-uterine Pregnancy; Dr. Parvin on the Care of the Perineum; Dr. R. S. Sutton on the Treatment of the Pedicle after Ovariotomy; Dr. Busey on the Influence of the Constant Use of High-heeled French Shoes upon the Health and Form of the Female; and Dr. Drysdale on the Ovarian Cell. The volume ends with Dr. Thomas's memoir of the late Dr. James Platt White, and the valuable index of gynæcological and obstetric literature of all countries for the year 1881.

C. M. G.

Intra-Thoracic Effusion. By NORMAN PORRITT, L. R. C. P. London, M. R. C. S. Eng., etc. London: J. & A. Churchill; Huddersfield: Alfred Taft. Pages 304.

This essay was awarded the Fothergillian gold medal for 1883 by the Medical Society of London, and deals mainly with effusion into the chest from the point of view of a surgeon, — its operative treatment by paracentesis or tapping, and thoracentesis or free incision. The point of election for both operations is in the back, the seventh interspace on the right, the eighth on the left; and a rule is given for finding the eighth space which is new. The position of the lower angle of the scapula when the arm is at the side is to be marked on the skin, and again when the arm is raised above the head; an inch below the middle of the line connecting these two points will always be found the desired interspace. While we cordially agree with our author in his preference for the back in tapping, the posterior axillary line seems to us better for the free incision, as the patient can then recline or lie upon his back without causing pain by pressure against the tube. The author seems to have discarded the aspirator, but uses a canula to which is fastened rubber tubing, the lower end of which is kept constantly immersed in a five per cent. carbolic acid solution. The trocar is passed through the side of the tubing and into the canula; when the pleural cavity has been reached the trocar is withdrawn, and the flow of fluid is started by the vacuum left in the canula, while the elasticity of the rubber closes the small hole in the tubing caused by the passage of the trocar. The risk of suction of the air in the tube into the chest is very slight, but, for precaution's sake, it is better to carbolize the interior of the tube before using it. Mr. Porritt makes no claim to originality in the use of the siphonage method, but we dwell on it here as we believe it to be in every way safer for the patient, though it requires more of the attendant's time, unless, indeed, "the patient may be left in charge of a trustworthy nurse" while the fluid escapes. We notice that the canula figured on page 21 is furnished with a lateral opening as well as the usual one at the end, the advantages of which are obvious.

In thoracentesis chloroform is preferred for children up to ten years of age, "for, unless very young, it is impossible to restrain their movements;" for all older patients ether is to be used. We are somewhat surprised at the length of double tubing which Mr. Porritt allows to remain in the chest after free incision, six inches in adults, four in children. On the sixth or seventh day the tubes may be shortened, and subsequently at each change of dressing, according to the progress of the case. If the opening is anywhere near the base of the chest we do not see what advantage is to be gained by the presence of six inches of double tubing, and we can see how cure may be retarded. It is almost needless to say that the strictest antiseptic precautions are enjoined.

On page 190 we find details of a case of large phthisical cavity at the base, which was opened and drained with happy results to the patient, the most successful case of the kind which we remember having seen in print.

Paracentesis pericardii should have received more extended notice in an essay so thorough and full of details as to all other aspects of operative interference with effusion into the chest. The author assigns as his reason for relative silence that he has never had occasion to perform the operation. Three of the four cases of free incision for purulent pericarditis with which we are acquainted have been reported since this essay was written, but Rosenstein's successful case was published in 1881.

The paper and typography are not quite up to the mark, and we have met with some half dozen oversights of the proof-reader not noted in the long list of errata which precedes the preface.

In conclusion we must express our obligation to Mr. Porritt for his valuable, painstaking, and nearly exhaustive essay, which should, and doubtless will, be widely read. That we have thought it necessary to criticise a few points may be taken as evidence that we have found the work worth careful study. F. C. S.

A Treatise on the Diseases of the Eye. By J. SOELBERG WELLS, R. C. S., etc. Fourth American from the Third English Edition, with copious additions, by CHARLES STEDMAN BULL, A. M., M. D., etc., etc. Philadelphia: Henry C. Lea's Son & Co. 1883. 8vo, 846 pages.

A new edition of a work as widely and favorably known as this requires notice only of the changes which have been made. The time between the publication of this and the previous edition is less than three years, yet the editor has evidently not been sparing of effort to incorporate in the book whatever of interest and value has appeared in the interval. As in former American editions, there has been little alteration of the original text, but the new material has been added in brackets. The arrangement of chapters has been somewhat altered. The section on Ophthalmia Neonatorum is wholly new, and the author recommends as prophylactic measures a modification of Credé's method. There is also a new section on Membranous Conjunctivitis. The views of Sattler on the parasitic origin of trachoma are given, but the method of treatment of trachoma and pannus by jequirity was published too late to find insertion. Additions are frequent throughout the book, some of the more important being on the operations of the author and Landolt for deformities of the lids; the comparative value of mydriatics; the theories of sympathetic ophthalmia and of glaucoma; optic neuritis in intracranial disease; and conjugate deviations of the eyes with bulbar lesions. The account of the latter condition we think might have been expressed more clearly. On the whole the work maintains its former high standard.

Medical and Surgical Journal.

THURSDAY, JANUARY 31, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

SOME OLD-TIME DOCTORS.

THE "Old Residents' Historical Association," of Lowell, Mass., has done much to collect and perpetuate by its published reports facts of interest which too often, for the lack of such an organization, have been allowed to perish with the lives of the possessors. A recent volume of their contributions, devoted to reminiscences of the early physicians of Lowell and vicinity, has been sent to us through the courtesy of Dr. John O. Green, President of the Association. The paper is prepared by Dr. D. N. Patterson. It is much to be wished that in other communities a similar labor of love might be performed in preserving the memory of a past medical generation. There is much for physicians of the present day to learn from the sturdy characters of such men, and the general public can appreciate from sketches like these the debt under which the community lies to the faithful services of the medical profession.

For reasons which are obvious the sketches published include only the names of men now no longer living, but we find among them several whose reputation had extended far beyond their own vicinity. Such are Dr. Elisha Bartlett, professor in at least five schools of medicine, among them the College of Physicians and Surgeons of New York. Dr. John C. Dalton, born in Boston, and returning hither in his later years to reap the fruits of his medical honors, and to be appointed senior physician to our then newly-built City Hospital, who yet spent the most active years of his life in Lowell and in its adjacent towns. An interesting story is related as to one of his early diagnoses. He had been selected by Dr. Wyman, on the retirement of the latter to the superintendency of the McLean Asylum, to succeed him at Chelmsford, being then twenty-three years of age. An old man from New Hampshire, while traveling through the town, was thrown from his sleigh and sustained an injury to his hip, which Dr. Dalton pronounced a fracture of the neck of the femur, and treated accordingly. The patient became restive under confinement, and insisted on being taken home. He had a large box made, into which he was placed with his apparatus and conveyed in a wagon a hundred miles, not in easy stages. Dr. Dalton naturally condemned the plan, but the patient persisted. Arrived home, he summoned a distinguished professor from Hanover, who said the bone was not fractured, and made the case the occasion of a lecture to his students on the evils of hasty diagnosis in young practitioners. Dr. Dalton hearing of this wrote the professor of his reasons for his diagnosis, but in such cases the weight of age generally carries the day in the public mind. After a few years the patient died, and Dr. Dalton promptly visited the place and requested an autopsy. A dissection showed a most interesting specimen of this fracture, and the young practitioner wrote his senior the particulars, and closed by saying that it *was* "very important in such cases to avoid a hasty diagnosis."

Space forbids us to cite other interesting anecdotes, or to do more than mention some of the other honored names to be found in this record. Dr. Rufus Wyman practiced for a number of years in Chelmsford, which is spoken of as the "mother town" of Lowell, and thence was called to the McLean Asylum at Somerville as its first superintendent, where he took an active part in planning some of the buildings, even drawing the architectural and working plans with his own hand. He was President of the Massachusetts Medical Society in 1840, and was the father of Drs. Jeffries and Morrill Wyman. Another president of the State Society was Dr. Elisha Huntington, also for eight years mayor of Lowell. Dr. Willard Parker, of New York (still living at an advanced age), was born in Chelmsford, but found chiefly in other cities the opportunities for earning the great name he has borne in surgery. Dr. Henry Kittredge, of Tewksbury, was a member of a family so noted for surgical skill in successive generations, that we are told that several physicians in New Hampshire applied to the Legislature to have their names changed to Kittredge in order thus to acquire the hereditary prestige. His biographer says of him that he made the tincture of common sense an important ingredient in every prescription which he compounded.

Taking these men as a whole we may say of them, in the words of Dr. Nathan Allen: "They inherited talents of a high order, and such was their calling and the circumstances surrounding them that they developed marked characteristics. It is doubtful whether any other city or vicinity in the State, except Boston, can present such a list of medical men. Some eight or ten physicians can be named among them whose equals in point of talent, education, and character it would not be easy to find."

Those who never won great renown outside their own town or neighborhood nevertheless left behind them a fragrant memory, and the work has been a good one, which has helped to preserve for a few years more the record of these faithful lives. To leave such a memory behind one is not an unworthy aim.

EMOTIONAL INSANITY AND THE DEFENSE OF NUTT FOR KILLING HIS FATHER'S MURDERER.

THE trial of Nutt, a young man not yet of age, in Pittsburg, for the deliberate murder of Dukes, who had slandered and outrageously deceived Nutt's sister,

and then killed her father for trying to protect her character, has resulted about as everybody had expected. If Dukes' offense was murder in the first degree, he should have been hanged. His acquittal raised a storm of indignation, to escape which, and, indeed, to save himself from the mob, he was obliged to take to flight. Under the circumstances, after so wretched a miscarriage of justice on the part of the courts, the sympathy of the community would naturally be with the youth who avenged his father's death and his sister's disgrace by killing the murderer of the one and the traducer of the other, a man who otherwise would have been allowed to go at large after having wantonly committed crimes which should meet with summary justice in any civilized community, and the failure to punish which must result in dueling, lynch law, or further crime.

It is unfortunate, however, that such offenses cannot be met by the laws of the land without resort to the plea of emotional insanity, the existence of which it is hard to think could have been believed by the judge and the jury, to the extent of considering it a disease of the mind involving irresponsibility. It is difficult to understand, too, how the medical witnesses could have supposed that in the case in hand there was actual mental unsoundness unless they considered the term emotional insanity to be a mere synonym of righteous indignation and natural passion over an egregious wrong. In either case the result is unfortunate for society. One unpunished crime does not justify another, and no community can long exist except under obedience to law, a disrespect for which has made homicide so common in some of our States in redress for injuries which the courts do not reach. Even that is not the only disastrous result of a verdict which in the least opens the way for another verdict of not guilty of murder by virtue of insanity in which no one believes. It brings medical expert testimony into contempt, and deprives of the reasonable defense of insanity many unfortunate persons, irresponsible, but whose unsoundness of mind is not evident to the lay mind, and who cannot create sympathy.

THE PRESERVATION OF THE ADIRONDACKS.

As a nation we are becoming aroused to the necessity of taking some action to prevent the total destruction of our forests. The mere loss of fuel and timber incident to their destruction is a small matter compared with the effect upon the water supply of potable springs and navigable rivers. The proposed action in regard to the preservation of the Adirondack forests is of more than local interest.

A bill has been introduced into the New York State Senate contemplating the formation of an Adirondack Park, within whose boundaries will eventually be comprised 1,700,000 acres of forest land. Altogether the State now owns about 750,000 acres in the Adirondack region, and of this, about 150,000 acres have reverted to it, for non-payment of taxes, during the past year. Within the next ten years it is believed that at this rate enough land will have reverted to the State to make the park the size contemplated in the bill. The whole is to be put into the charge of a superintendent, whose duty shall be to protect it from depredations. It is a question, however, whether this measure sufficiently provides for the end which it is designed to accomplish, namely, the conservation of the sources of water supply for the upper Hudson and for the streams which feed the canals and fertilize the agricultural lands of the northern part of the State. It is possible that this tract of 1,700,000 acres may not be large enough for the purpose, and even if this is the case, it would seem desirable that the bill should be amended in such a way as to secure the protection of the forests on the 1,000,000 acres which have not yet reverted to the State, since the work of destruction is said to have already gone on to such an extent as to seriously threaten the water supply.

MEDICAL NOTES.

— The *Polyclinic* (January 15th) contains the report of the treatment of two cases of obstinate intermittent fever in the hospital service of Dr. J. Solis-Cohen, by the hypodermic injection of the double salt of muriate of quinia and of urea, in accordance with the suggestion of Dr. Bartholow. Ten grains of the salt (the formula for which is given in the last edition of the United States Dispensatory) was injected at a dose, and the effect on the chills and the malarial cachexia in general was apparently most beneficial.

— The same journal gives an account of the extraction of a leech from the larynx of a man, aged sixty-four years, who had entertained the unwelcome guest for fifteen days before he presented himself at the *Policlinica de la Escuela de Medicina de Sevilla*. The patient was unaware of the cause of the obstinate hæmorrhages, associated with aphonia, constant harassing cough, difficulty of deglution, and great embarrassment of respiration, for the relief of which he consulted Dr. Sota; symptoms which, in connection with the family history of the patient and the history of the attack, led at first to the supposition of phthisis; and, when nothing abnormal was found upon physical exploration of the chest, to the idea of primary tuberculosis of the larynx. But laryngoscopic inspection at once revealed the nature of the case, the leech being seen adherent to the pad of the epiglottis, immediately above the anterior commissure of the vocal bands, extending upward and backward, so that its tail rested on the apex of the right supra-arytenoid cartilage. Notwithstanding the intractability of the patient, whose starts and movements interfered with the first attempts at extraction, Dr. Sota succeeded in removing the animal from its dangerous situation *per vias naturales*. It appears that while overheated and covered with perspiration, the patient had swallowed a draught of cold water, and immediately experienced a constriction of the throat, followed by the symptoms above alluded to, as well as a continual tickling in the larynx.

— A little careful inquiry by the officers of medical organizations would undoubtedly show numerous extravagances which if avoided would leave money suffi-

cient to maintain the *Index Medicus* with scarcely any necessity for relying on private subscription. It is not only the honor of the American medical profession which is at stake, but it is also the practical question of maintaining the present advantage of a general index in our own language, and gotten up in a style which makes it a pleasure to consult its clearly printed pages. — *Polyclinic.*

— The *Medical and Surgical Reporter* calls attention to an insult perpetrated upon the medical profession by the Red Star Line Atlantic Steamship Company, which, contrary to the custom of all other lines, has within the last year ordered its surgeons to mess at the second-class table, and ranks them in other respects as second-class passengers. This is an indignity which has been keenly felt as such by all its medical officers; some have resigned in consequence, others have waited, trusting that the remonstrances of members of the profession to the company would have some effect. So far from this, the Red Star Line has added another insult to the profession by passing over its protests with contemptuous silence. In every line except the above the surgeons are assigned quarters and mess with the first-class passengers.

— The daily press reports 542 suicides for 1883 in Paris, a gain of sixty-three over 1882. The choice of means of death shows that hanging is not as popular as it is in England, for while only eighty-one hung themselves, 217 used firearms, and 148 drowned themselves. By thirty-seven, the more scientific expedient of burning charcoal in closed rooms was adopted.

— The *Gazette* protests against a pupil of the Boston common schools being sent as a messenger by the teacher to a house in which there was contagious disease, and represents the great danger incurred of his carrying contagion into the school on his return. It states that the Board of Health, more than a year ago, called the attention of the School Committee to this practice, and asked that it be stopped, but that the School Committee had declined to take action on the subject.

— Dr. Solomon M. Whipple, of New London, N. H., ex-president of the New Hampshire Medical Society, and a well-known physician throughout the State, is dead, aged sixty-three.

— Rev. R. Heber Newton, in a paper on the Obligations of Society towards the Insane, pleads for schools for the special training of nurses for the insane as follows:—

"If trained nurses are coming to be regarded by our best physicians as indispensable to the proper care of the diseased to-day, how much more necessary are they in the care of the mind diseased! There is needed a knowledge of the symptoms of this most miserable of sicknesses and of the methods of dealing with them, which demands special mental training. There is needed, as well, a power to rule with quiet firmness, a gentleness of tone and manner, a delicacy of thought and feeling which requires a special moral training." "Such an institution," he concludes, "properly founded and conducted, would call to the ministration upon this most pitiful form of misery the talent and character of a superior order of men and women, as always follows from the ennobling of a vocation. Hosts of gentlewomen wait new openings for honorable self-support, and such a vocation would command their refined and sympathetic service with benign results."

NEW YORK.

— At a stated meeting of the County Medical Society, January 28th, Dr. Charles Heitzman read a paper on Recent Researches in Embryology, and Dr. W. G. Wylie a memoir of the late Dr. J. Marion Sims.

— The seventeenth annual report of the State Board of Charities was presented to the Legislature at Albany on the 24th of January. The greater part of the statistics in regard to the insane of the State was previously given in the Governor's message at New Year's. In the visitations to the almshouse in the different counties during the year special attention was devoted to investigating the character and condition of the children in these institutions, and they were found to be generally vicious and depraved. A few were healthy and intelligent, but many were crippled, paralytic, epileptic, idiotic, or otherwise diseased, while the accommodations for their proper care and nursing were, as a rule, totally inadequate. The number of insane, feeble-minded, and otherwise infirm and helpless individuals from outside localities, who had no valid claim on the charities of the State, committed to New York institutions since October 22, 1883, had been 10,965, but under the examinations of the Board the former homes of 6320 of these had been traced to other States and countries, and they had been sent where they respectively belonged. In regard to the immigration and the shipment of chronic paupers and helpless dependents to this country, the Board urges that the prompt return of these classes costs less than their maintenance and care in the asylums, hospitals, and almshouses of the State for three months, and it recommends another small appropriation by the Legislature to continue this work until Congress shall protect the State against the influx and consequent life-long support of chronic foreign paupers pushed upon it through the various sea-ports and by way of Canada.

— At the annual meeting of the Hospital Saturday and Sunday Association, held January 21st, it was stated that the late collections amounted to date to the sum of $40,082.03, but as contributions were still being daily reported the treasurer asked that the books might be left open until February 1st. The secretary reported that 210 churches of various denominations had already sent in their offerings, and that there were about 100 others which had promised to take up collections, the receipts from which would probably amount to about $3000. The year previous only ninety-four churches and chapels contributed.

— The Rev. Dr. Howard Crosby, late chancellor of the University of the City of New York, has published a letter in which he pays the following tribute to the present excellent condition of Bellevue Hospital: My duties have led me to Bellevue Hospital

for the past twenty years, and I am constrained to speak of the vast improvement manifest in every department of that important institution. The order and cleanliness of the wards, the efficiency of the attendants, the skill and faithfulness of the physicians, and the courtesy of all concerned, are fit subjects for praise and pride. But above all the admirable work of the trained nurses should be recognized and commended. These refined ladies, full of enthusiasm and devotion, and ably prepared for their responsible duties, are angels of mercy to the sick and suffering, and their tender regard for the patients is itself a healing balm. . . . There was a time when thoughts of Bellevue were not savory, but now I know no place where I should rather be an invalid to receive the wise and gentle attention of experienced and sympathetic guardians.

Correspondence.

THE TREATMENT OF HIP-JOINT DISEASE. EXTENSION BETTER THAN EXCISION.

MR. EDITOR, — I was much interested in the discussion in your journal upon excision of the head of the femur in hip-joint disease. I must acknowledge, however, that I was somewhat surprised to find that the operation was advocated and so often practiced as was represented during the discussion.

I had supposed that since my introduction of the treatment of diseases of the joints by elastic or continued extension that there had been no occasion for excision of the head of the femur.

As to the frequency of this disease of the hip proving fatal, at the present time, it was entirely new to me. It certainly is at variance with my experience in the treatment of such cases, so much so as to render it difficult for me to realize its possibility, taking it for granted that the treatment was by the present received mode, both in this country and in Europe.

Some thirty years since I began the treatment of joint diseases by continued extension, and between the years 1850 and 1860 published in the medical journals many papers upon the subject, endeavoring to so bring my method of treatment before the profession that they could understand its principles, and thus be enabled to apply the treatment correctly, and obtain the favorable results that had followed it in my hands.

In giving the results of the treatment of hip disease, as practiced by me for so many years, I am embarrassed by the feeling that my statements will be distrusted by the gentlemen engaged in the discussion, when they compare them with their experience. I can say, without equivocation, that among the *vast* numbers that have been under my care, *not one* has succumbed to the disease; and that in those cases that came under my care in the early stages they recovered without deformity or lameness. After the head of the bone has been partially destroyed, it cannot be expected that the treatment will restore it, although the disease was arrested at once by the treatment.

This mode was so fully described in my work entitled Conservative Surgery, that it would seem superfluous to describe it here, yet there are some points that appear not well understood, or at least not fully appreciated, that are essential to good success.

I will mention first the use of the short splint, where the adhesive straps take hold only of the thigh. The short splint was used by me and discarded some time before Otto & Rynders brought out the one that is called Dr. Sayre's splint. I found that the limb would always shorten while wearing it, for the skin of the whole body above will elongate by the traction, thus allowing the limb to steadily shorten. It does not *stop* the destruction of the parts, only retards it, inasmuch as it removes the pressure.

My adhesive straps were not only applied to both sides of the whole length of the limb, but two strips commenced at the outer maleolus and wound around the limb, taking hold of the strip upon the inside of the limb, also compressing the muscles in the calf of the leg, also of the thigh, where extension was made by the long splint. This arrangement of the strips gives a sure hold of the limb, one that will not yield.

Again there is an important, I may say an all important, difference in the perineal band used by me and other instruments. In all the splints that have come under my observation, they are made with only one band, and that for extension alone, whereas in my instruments there is an outside inelastic band, which, after the extension is made and the outside inelastic band is buckled tight, prevents the retraction or shortening of the limb either by the contraction of the muscles or by the weight of the body. When the short splint is used the recovery, as a rule, is very much like that without treatment, except, perhaps, the position of the limb and the freedom from suffering.

Now if you want a speedy, and at the same time a perfect recovery, perfect considering the freedom from the loss of parts when the treatment commences, you must not allow the head of the bone to impinge upon the upper part of the acetabulum, as this contact is liable, if it remains for any length of time, to destroy all that has been gained before. The bony parts involved can never heal so long as they come in contact, as it is this pressure that keeps up the destruction of the parts.

Some of the speakers advised free opening of the abscesses.

Before the adoption of my treatment I had seen abscesses opened, followed by hectic fever, night sweats, and death. Since the adoption of my plan of treatment there has never been an unpleasant symptom following the opening of an abscess, however reduced the patient or unpromising the constitution.

After opening the abscess and discharging the contents I have washed it out with warm water, syringing it two or three times, then injecting chlorine water two or three times according to the sensibility of the sac. I introduce a small tent to keep an opening, and apply a compress. In this way the walls of the sac unite, leaving only a sinus for the discharge of the pus from the diseased bone. This reduces the discharge to a very small quantity, so small as not to affect the health or retard the recovery.

In this connection allow me to ask what will destroy the patient? He can eat, drink, and sleep well, and have not enough discharge to affect his health.

Some spoke of anchylosis being the most favorable result, and the one to be sought for in treatment.

So far as my experience goes this never takes place between ulcerated surfaces of bone. A fixed state of the joint caused by a shortening of *all* the soft parts connected with the femur at the joint is what is generally termed anchylosis. I have yet to see a case

where there is bony union. I have produced free motion after this fixture of the joint for seventeen years, accomplishing it without pain or suffering; doing it in the same way that I have reduced dislocations of the hip of twelve years' standing.

HENRY G. DAVIS, M. D.

NEWTON, MASS. (formerly of New York City).

Miscellany.

PREGNANCY AND MORPHINISM.

DR. FÉRÉ (*Revue Médicale*, November 17, 1883) gives an account of the case of a young woman addicted to the opium habit to the extent of subcutaneous injection of twenty-four centigrammes of morphia daily, who came to Paris when six months pregnant to be cured of her habit. The case was difficult for the reason that as soon as the daily dose was diminished by a half a centigramme, violent uterine colic ensued which threatened to bring on miscarriage. However, with great precautions, times of cessation of treatment, and even a temporary return to stronger doses when the uterine contractions became too marked or the fœtal movements were violently increased, the daily dose of morphia was reduced almost one half, and on the day of confinement, May 6th, the patient only took thirteen centigrammes. The labor, conducted by M. Tarnier, was natural. During the next eight days the allowance of thirteen centigrammes was given daily. But on attempting to resume the reduction, there were renewed uterine contractions with suppressed lochia. It was necessary to temporize as before, but on the 3d of June the patient was taking only eight centigrammes. At this point the injections were abruptly stopped. There was violent colic, nausea, and diarrhœa. But after a few days they ceased, and the patient was finally cured of her habit, the cure remaining permanent.

Dr. Féré insists on two interesting points: In the first place the necessity of proceeding to demorphinize pregnant patients only with the greatest precautions against setting up uncontrollable uterine contractions and premature labor, to say nothing of other accidents which may be caused in the mother. Secondly, the necessity for moderation in the process is not less for the sake of the fœtus, which undergoes disturbance and convulsions in the womb when deprived suddenly of the stimulant to which it has become accustomed. The fœtus after birth may also suffer from the sudden demorphinization accompanying the change in its condition, and the writer thinks it may be proper in certain cases to pursue for the sake of the child the use for a time after birth of the morphia, which it could not safely be at once and wholly deprived of.

A CASE OF PLAGIOMICROCEPHALIA.

THE *London Medical Record* (December, 1883) contains a case of asymmetrical microcephalia accompanied by remarkable anomalies of the motor system. A similar case is to be found in the May issue of the same journal. The former case is from *Vratch*, and is as follows: —

Dr. M. Lukin, of Cronstadt, publishes the detailed post-mortem description of a microcephalic boy, aged four. The antero-posterior diameter of the head was twelve centimetres, the transverse nine and a half, the diagonal fifteen. The skull had a dolichocephalic form, and was markedly asymmetric (more developed on the right than on the left side). The cranial bones were thin, with very scanty spongy substance. The brain weighed only 420 grammes. [In Rudanovsky's case, says the reporter, in the Proceedings of the St. Petersburg Society of Psychiatres, 1880, it weighed 258.72 grammes in a patient aged seven years and eight months; in Professor Merzejewski's case 369.053 in a patient aged sixty; in Theile's 300 in a patient aged thirty; in Sander's 372.444 in a patient aged eighteen.] The measurements of the brain were these: The length of the hemispheres was ten centimetres; their height in the middle 5.3; their breadth at the level of the parietal lobes nine; the length of the frontal lobes, six; of the occipital 1.8; of the cerebellum 4.5; the breadth of the latter seven; its height 3.7. Two centimetres of the length of the cerebellum remained free, that is, were not covered by the occipital lobes. On the left side there were absent the anterior part of the fissura olfactoria, the whole gyrus rectus, fissura transversa (between the fissuræ supraorbitales longitudinales), gyrus frontalis medius, gyrus uncinatus, fissura parieto-occipitalis, and fissura præcentralis superior. On the right side the fissuræ transversa and calcarina were absent. On both sides the lobuli paracentrales, quadrati, and cuneiformes were very narrow and very indistinctly separated one from another. During his life the boy presented the following phenomena: He was very cross and violent; in fits of anger he bit his own hands or everybody who interfered with him; he did not learn to speak; he asked for food by gestures; he was not able to take his food by himself (though he swallowed well); he invariably refused to drink; he began to walk at about two years of age; up to his very death he invariably walked only backwards, notwithstanding all his mother's efforts to teach him the normal walk. According to Dr. Khrabrostin, who on two occasions saw the patient with his curious method of locomotion, the boy usually backed pretty rapidly, always carrying his head thrown far backwards.

TYPHOID AND MALARIAL FEVERS IN CONNECTICUT.

IN regard to the prevalence of typhoid and malarial fevers during the month of October the secretary of the Connecticut State Board of Health reports as follows: —

The weather has apparently been favorable to the development of malarial fevers, and an increased prevalence is quite generally reported. While perhaps rather more cases of intermittent fever, that is, acute tertian ague, have been seen this season than for several years in the districts where malaria has been prevalent for some time, yet the prevalent type generally is the typho-malarial and the less clearly defined varieties of malarial diseases. Typhoid fever, although steadily increasing in frequency, does not apparently so completely to drive out malaria as malaria appeared to drive out typhoid fever when it first commenced to extend over the State, so that for years not a case of typhoid fever occurred over large areas, and it lost place among the ten principal causes of death throughout the State.

That the decreased frequency of typhoid was entirely independent of the malarial invasion now is quite clear.

The return of typhoid is also not dependent upon the decrease of malarial diseases, as we see it side by side with all varieties of ague, not only where the latter has longest remained as one of the regular diseases of the region, but also where malarial diseases are entering territory hitherto never occupied, so far as human knowledge can determine, by any form of ague; and also where having existed quietly for several years malarial diseases become epidemic, leaving but a small percentage of the people unaffected. The subject is too complicated to discuss here, but the increased frequency of both malarial diseases and typhoid fever are interesting features.

HALLUCINATIONS FROM SALICINE.

A WRITER in the *Australasian Medical Gazette* (November, 1883) gives an account of some mental phenomena following large doses of salicine, which, though not entirely unknown heretofore, are sufficiently unusual to be interesting, and were, moreover, recorded as the observations of a medical man on his own person. A peculiarity of this case was the perception of a number of musical airs, in a regularly recurring order, but having no objective reality. The writer says: —

"On July 9th I took to my bed with, as I thought, a slight attack of acute rheumatism. I treated myself (not liking to trouble Dr. ——) with alkalies, lemons, and entire abstinence from alcohol. I remained in bed for all the week, and, not getting much better, commenced to get very anxious about my practice, and determined to try salicine in large doses, such as I have frequently seen mentioned in the *Lancet*, although I had never given it quite so heroically to patients. Accordingly, on Sunday, July 15th, I took four doses, at intervals of only two hours, of forty grains of salicine in each dose. It made me drowsy, and I slept most of the afternoon. Just after dark I awoke, and found myself apparently mad, and yet conscious of my own madness. There seemed to be all sorts of people about me and in the room, and yet I was conscious that they were fanciful creations of the mind, and had no fear or dread of them. They were all, so far as I can recollect, human in appearance, and all strangers to me. The music had now commenced, and it was so natural that I said to my wife that I had never heard (it was Sunday night) the church music so far off before. The music gradually got louder and more defined, until it settled down to one perpetual repetition in regular order — much after the fashion of a musical box — of a certain six airs, one of which had a choral accompaniment, the human voices being perfectly distinct and audible. Only one of the airs was known to me, namely, 'Scenes that are Brightest,' from Maritana. All the others were strange. I am not a musician, but I know enough to be sure that the time kept was perfect. This lasted for forty-eight hours, and I was nearly mad in reality at the end of that time from the constant apparent noise and din. The chloral did me some good, but immediately on awakening from a deep chloral sleep *my band*, as I got to call it, would begin again. It gradually wore away on the third day, but for some days afterwards I occasionally heard one of the tunes, and perhaps part of another. I was, throughout, much interested in all the symptoms, and recognized from the first what had happened, and that the salicine was to blame, but I was uncertain how the case might end. I have had a long and slow convalescence, suffering a great deal from occasional pains and great weakness, and am now slowly coming round."

PAROVARIAN CYSTS.

DR. GOODELL recently exhibited two cysts of the parovarium before the Obstetrical Society of Philadelphia (*Medical and Surgical Reporter*, January 5th). Both patients got well; he indeed had never lost a patient from whom he had removed a parovarian cyst. In both cases a correct diagnosis was made previous to the operation. Regarding the differences between this tumor and the cyst of the ovary, he remarked that one interesting diagnostic point was the complete absence of the *facies ovariana*. The color in the cheeks was good, and the countenance was free from the anxious expression present in cases of ovarian tumor. One tumor had existed for ten years, the other for one. Another important point in the differential diagnosis is not only the flaccidity of the tumor but its variable degrees of flaccidity. Upon inspection, it is seen to reach to the sternum, and seems to occupy a large portion of the abdominal cavity, but where the hands are placed upon its sternal edge it can be compressed to the level of the umbilicus. An ovarian cyst, on the contrary, is hard and uncompressible. Exceptions to this rule are very rare, that is, either a tense parovarian cyst or a flaccid ovarian one. A third important distinguishing point is the long time — ten years in one case — which the tumor existed, and further, without marked deterioration of health. After being tapped these tumors usually refill, but occasionally they do not, and a cure is thus brought about. The fluid withdrawn has been in every case limpid and generally colorless, but it has sometimes had in his experience an emerald tint. These tumors are generally free from serious adhesions, but if, in an operation for the removal of one, adhesions should exist where for any reason their forcible separation would be unadvisable, or the cyst were intra-ligamentous, he would not hesitate to leave the adherent portion of the cyst wall, or the whole cyst itself, after making a big hole in it, as the fluid it secretes is bland and unirritating to the peritonæum.

Any one examining one of these cysts for the first time would consider it to be of ovarian origin, for it is only by patient search that the ovary can be found spread out over the cyst wall. The microscope will decide with certainty in any otherwise doubtful case. The tumor is covered with a beautiful net-work of veins.

When a cyst of the parovarium exists on one side, the ovary of the opposite side is usually found to be diseased and should be removed. In these cases the remaining ovary was seen to be enlarged, and the site of a small ruptured cyst was pointed out. The Fallopian tube was also enlarged, and the terminal vesicle of the Fallopian tube, or the hydatid of Morgagni, was enlarged and cystic. This hydatid sometimes attains the size of an orange, and often ruptures spontaneously without any bad effects. A few years ago one of these small cysts ruptured while he was making an examination of the patient to ascertain its character.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 19, 1884.

Deaths reported 2574 (no reports from Cincinnati and Buffalo): under five years of age, 840: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 430, consumption 432, lung diseases 407, diphtheria and croup 164, scarlet fever 66, typhoid fever 40, measles 38, diarrhœal diseases 34, malarial fever 25, whooping-cough 21, puerperal fever 19, cerebro-spinal meningitis 11, erysipelas nine, small-pox two, yellow fever one. From *measles*, District of Columbia 13, Baltimore 11, New York five, Pittsburg three, Brooklyn and Chicago two each, Charleston and Nashville one each. From *diarrhœal diseases*, New York eight, Boston six, New Orleans five, Philadelphia four, Baltimore and Charleston two each, Brooklyn, District of Columbia, Providence, New Haven, Cambridge, Lynn, Springfield, and North Adams one each. From *malarial fever*, New York and St. Louis seven each, New Orleans five, Brooklyn, Chicago, and Baltimore two each. From *whooping-cough*, New York six, District of Columbia three, Brooklyn, New Orleans, and Cambridge two each, Philadelphia, Chicago, Boston, Gloucester, North Adams, and Arlington one each. From *puerperal fever*, Boston and Milwaukee four each, St. Louis three, Philadelphia, Chicago, Baltimore, and Charleston two each, New York one. From *cerebro-spinal meningitis*, New York three, Chicago and District of Columbia two each, Philadelphia, Boston, Milwaukee, North Adams, and Dedham one each. From *erysipelas*, New York three, Philadelphia two, Brooklyn, Chicago, Boston, and Gloucester one each. From *small-pox*, Philadelphia and St. Louis one each. From *yellow fever*, New York one.

One case of small-pox was reported in Holyoke; scarlet fever 41, diphtheria 30, typhoid fever 14, and measles three in Boston.

In 92 cities and towns of Massachusetts, with an estimated population of 1,285,557 (estimated population of the State 1,922,530), the total death-rate for the week was 20.00 against 18.00 and 17.41 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 5th, the death-rate was 22.2. Deaths reported 3731: acute diseases of the respiratory organs (London) 387, scarlet fever 112, measles 100, whooping-cough 103, fever 51, diphtheria 30, small-pox (Birmingham eight, Sunderland seven, London and Liverpool six each, Manchester one) 28. The death-rates ranged from 12.1 in Norwich to 31.3 in Cardiff; Bradford 17.7; Nottingham 19.1; London 21.6; Birmingham 21.9; Sheffield 23.8; Liverpool 23.9; Leeds 26.5; Manchester 29.1. In Edinburgh 21.8; Glasgow 29; Dublin 28.7.

For the week ending December 29th, in 162 German cities and towns, with an estimated population of 8,472,338, the death-rate was 24. Deaths reported 3912; under five years of age, 1812; consumption 542, lung diseases 447, diphtheria and croup 281, diarrhœal diseases 118, scarlet fever 66, whooping-cough 60, measles and rötheln 58, typhoid fever 53, puerperal fever 25, small-pox (Schwerin one) one. The death-rates ranged from 12.8 in Wiesbaden to 32.1 in Leipzig; Königsberg 26.6; Breslau 30.4; Munich 25.8; Dresden 22; Berlin 23.5; Hamburg 29.5; Cologne 18.9; Frankfort a. M. 15.2; Strasburg 29.7.

For the week ending January 5th, in the Swiss towns, there were 26 deaths from lung diseases, consumption 25, diphtheria and croup 13, diarrhœal diseases seven, whooping cough four, typhoid fever four, scarlet fever three, puerperal fever three, measles one, erysipelas one. The death-rates were, at Geneva 19.5; Zurich 22; Basle 16.7; Berne 29.4.

The meteorological record for the week ending January 19th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING JANUARY 26, 1884.

ANDERSON, F., passed assistant surgeon, granted leave of absence for six months.

WHITING, ROBERT, passed assistant surgeon, detached from the Naval Hospital, Norfolk, and ordered to the U. S. Receiving Ship Colorado, New York.

FITTS, H. B., assistant surgeon, detached from the U. S. S. Jamestown and ordered to U. S. Coast Survey Steamer Gedney.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE HOSPITAL SERVICE, OCTOBER 1, 1883, TO DECEMBER 31, 1883.

BAILHACHE, P. H., surgeon. Relieved from duty at Cape Charles Quarantine Station. October 13, 1883.

Detailed as member of board to examine candidates for promotion. October 30, 1883.

Granted leave of absence for thirty days. November 27, 1883.

HUTTON, W. H. H., surgeon. Granted leave of absence for twenty days. October 1, 1883.

WYMAN, WALTER, surgeon. Detailed as member of board to examine candidates for promotion. October 30, 1883.

To proceed to Norfolk, Va., to investigate the conduct of the service at that port. December 31, 1883.

LONG, W. H., surgeon. Leave of absence extended ten days. October 26, 1883.

MURRAY, R. D., surgeon. To proceed to Ship Island Quarantine Station. October 17, 1883.

To inspect sites for quarantine stations. November 30, 1883.

Granted leave of absence for twenty days. December 18, 1883.

SMITH, HENRY, surgeon. Granted leave of absence for twenty-five days on account of sickness. October 13, 1883.

Relieved from duty at Norfolk, Va. October 17, 1883.

To report to Surgeon Sawtelle, at New York, for temporary duty. November 27, 1883.

Relieved from temporary duty at New York and placed on waiting orders. December 31, 1883.

FISHER, J. C., passed assistant surgeon. When relieved by Assistant Surgeon Banks to proceed to New York for duty. October 29, 1883.

Granted leave of absence for thirty days. November 28, 1883.

GOLDSBOROUGH, C. B., passed assistant surgeon. Granted leaves of absence for thirty-two days on account of sickness. October 12, October 20, and November 1, 1883.

IRWIN, FAIRFAX, passed assistant surgeon. To proceed to Norfolk, Va., and assume charge of the service, relieving Assistant Surgeon Glennan. October 16, 1883.

MEAD, F. W., passed assistant surgeon. To proceed to Portland, Oregon, inspect the service, and report the condition of Assistant Surgeon Devan. December 5, 1883.

To return to station, Port Townsend, Washington Territory. December 18, 1883.

COOKE, H. P., passed assistant surgeon. To proceed to Charleston, S. C., for duty. November 27, 1883.

BANKS, C. E., assistant surgeon. Detailed for temporary duty at Georgetown, D. C. October 11, 1883.

Granted leave of absence for thirty days. October 12, 1883.

BENNETT, P. H., assistant surgeon. Placed on waiting orders. December 15, 1883.

Granted leave of absence for thirty days. December 22, 1883.

Upon expiration of leave of absence to proceed to Detroit, Mich.. for duty. December 29, 1883.

PECKHAM, C. T., assistant surgeon. To proceed to Wilmington, N. C., and assume charge of the service, relieving Passed Assistant Surgeon Irwin. October 16, 1883.

DEVAN, S. C., assistant surgeon. Granted leaves of absence for ninety-five days on account of injury and sickness resulting therefrom. November 15, December 5 and 22, 1883.

BEVAN, A. D., assistant surgeon. To proceed to Portland, Oregon, and assume charge of the service. December 29, 1883.

GLENNAN, A. H., assistant surgeon. To proceed to New Orleans, La., for duty. October 17, 1883.

WASDIN, EUGENE, assistant surgeon. To proceed to Mobile, Ala., for temporary duty. October 11, 1883.

To proceed to Galveston, Texas, for temporary duty. November 17, 1883.

PROMOTIONS.

BENSON, J. A., passed assistant surgeon. Promoted and appointed passed assistant surgeon, by the Secretary of the Treasury, from October 1, 1883. October 4, 1883.

BANKS, C. E., passed assistant surgeon. Promoted and appointed passed assistant surgeon, by the Secretary of the Treasury, from November 1, 1883. November 6, 1883.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting of the Society will be held in the Medical Library Rooms, on the second Thursday of February, at four o'clock P. M. F. S. Billings, D. V. S., will read a paper upon Eclampsia in Woman and in the Cow. Profession invited.

HENRY M. FIELD, M. D., *Secretary*.

BOOKS AND PAMPHLETS RECEIVED. — The International Encyclopædia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery by Authors of Various Nations. Edited by John Ashhurst, Jr., M. D., Professor of Clinical Surgery in the University of Pennsylvania. Illustrated with Chromo-Lithographs and Wood-Cuts. In Six Volumes. Vol. IV. New York: William Wood & Company. 1884.

Transactions of the American Surgical Association. Volume the First. Edited by J. Ewing Mears, M. D., Recorder of the Association. Philadelphia: Printed for the Association, and for sale by Presley Blakiston & Co. 1883.

CEREBRO-SPINAL MENINGITIS. FIVE CASES. ONE, OF THE FULMINANT (FOUDROYANT) TYPE, TREATED BY SUBCUTANEOUS INJECTION OF APOMORPHIA, MORPHINE, AND ATROPINE; RECOVERY. ONE AUTOPSY.[1]

BY A. L. MASON, M. D.

November 13, 1881. G. H., a healthy young gentleman of twenty-one, was seized without premonition, immediately after a hearty dinner, during which he had been in his usual spirits, with sudden vertigo. He staggered with assistance to a sofa, and became unconscious, with pallid countenance, clammy skin, and no pulse. I saw him fifteen minutes later, at 8.45 P. M., when the condition was as follows: semi-conscious, eyes vacant, pulse 70 of fair strength, breathing shallow, skin moist, hands and feet cold. Movements indicated that there was pain or distress in the head and cardiac region. In a few minutes convulsive shivering and twitching of the lips and jaw were observed. Ammonia was applied to the nostrils and hot bottles to the extremities. An attempt to swallow brandy and water caused a convulsion of great severity, the muscles of the neck, back, and thorax being in a state of prolonged contraction, with upward rolling of the eyes and clenching of the jaws. The breathing stopped, the heart became feeble, there was cyanosis and, apparently, impending asphyxia, which was averted by the gradual relaxation of the spasm. These convulsions recurred in rapid succession, and seemed to be very exhausting. The friends could assign no possible cause for the symptoms. The patient had never had a similar attack; there was now no frothing at the mouth, paralysis, or vomiting. There had been no previous complaint of any discomfort whatever up to the moment of attack; uræmic or irritant poisoning seemed improbable; cerebro-spinal meningitis was not prevalent, and it was not until the following day that a probable diagnosis could be arrived at.

The state of the patient was critical, and I immediately sent for Dr. J. Collins Warren to consult with me, requesting him to bring a stomach pump and ether. Dr. Warren came at 9.30 P. M., one hour after the beginning of the attack, and he also brought some apomorphia, which proved to be of the greatest possible service. The patient, who was a large, heavy man, was with difficulty carried up to bed, mustard was applied to the extremities, and ether was administered. The latter was found to be of no use, as the convulsions were excited to an alarming extent by the first inhalations. At 10.30 P. M. one sixth of a grain of muriate of apomorphia was injected under the skin, and in eight minutes the stomach was emptied, without retching, as if it had been turned inside out. A basinful of solid food, quite unchanged, was evacuated. Relief followed. The face, which had been congested, became pale, free perspiration ensued, the convulsive action subsided, the pulse was 72, and the patient rested quietly until five A. M. without further treatment.

November 14th. At nine A. M. there was a return of convulsions of the same type. The patient was unconscious; face dusky, pupils dilated, head drawn back, with rigidity of cervical muscles. There was inability to swallow and retention of urine. A pint, normal in character, was drawn by catheter.

At 11.30 A. M. Dr. Warren again saw the patient in consultation. It was determined that he was suffering from cerebro-spinal meningitis, and a guarded prognosis was given.

The bowels were emptied by a large stimulating enema, six grains of calomel were given, ice was applied to the head, and leeches to the nucha. The leeches and ice were of no benefit, however, because their application caused general convulsions, with opisthotonos, and after a few minutes it was evident that the subcutaneous injection of morphia was the only remedy likely to prove of any value. The patient was kept constantly under its influence, one eighth grain of morphine combined with one one hundredth of atropine being given at varying intervals for many days. Owing to the inability to swallow, nutritive enemata of milk, beef-tea and brandy were given every three hours. Bromide of potassium was also administered by the rectum. The calomel acted once.

November 15th. Drs. Borland, Warren, and William Appleton saw the patient in consultation. Dr. Borland, who had been the family physician for many years, concurred in the diagnosis and treatment. The condition thirty-six hours after the attack began remained about the same. But the convulsions were partially controiled, the enemata were retained, the kidneys secreted about two pints of normal urine daily, which was drawn by catheter, there was a good pulse of 85, and little or no fever. Still the condition was dangerous, and during the following days Dr. Warren met me frequently in consultation. After the first forty-eight hours the patient was placed under the constant medical care of Dr. Charles P. Strong, who for twelve nights gave him the benefit of much judicious attention, which contributed greatly to his recovery. From Dr. Strong's notes I make the following extracts regarding the progress of the case: —

November 15th, third night. The convulsions were recurring in series of three or four, with several hours' intermission, with less severity, but the muscles of the face, neck, and extremities were in a state of constant spasm, producing twitching movements, which were, however, to a great extent under the control of morphine.

The sensibility to external impressions had become very great, sudden admission of light, shutting the door, and the like, producing convulsions. There was hyperæsthesia of the whole body, most marked over the cervical vertebræ however, where the slightest touch produced a spasm.

Pulse, temperature, and respiration were normal, but the pupils were widely dilated. Slight epistaxis. Nourishment was given by enema. Subcutaneous injections of morphine, grain one eighth, atropine grain one one hundredth, were required at eleven A. M., 2.45 and ten P. M.

During the third day the patient swallowed two ounces of milk by teaspoonfuls, though showing no other consciousness.

November 16th. Aside from two convulsions produced by enemata the night was passed very quietly. Hyperæsthesia of the neck was fully as marked as on previous days, and several convulsions were induced by the patient's putting his hands on that region. The pupils were a little less dilated than on the preceding days, and pulse and temperature both normal.

[1] Read before the Boston Society for Medical Improvement, January 28, 1884.

Bromide of potassium was given in twenty-grain doses, and to the amount of a drachm and a half daily during the rest of the sickness, being omitted sometimes because of bromism, which was readily induced. Nourishment was given through a soft rubber tube, around which the patient's lips were held. There were no convulsions between eight A. M. and 2.30 P. M., or 2.30 and 10.30 P. M. Temperature 99°; pulse 65.

Subcutaneous injections of the same amount as yesterday were given at 4.30, 8, and 10.30 A. M. 2.30 and 10.30 P. M.

November 17th. There were but two convulsions during the night, and the muscular twitchings were much less marked. Considerable nourishment had been taken, and the patient's general appearance was improved. There seemed at times a semi-conscious condition, as shown by the patient opening the mouth when told, smacking his lips in a peculiar manner when he wanted water, and at such times refusing to drink anything else. He could close his lips around the tube when it was put in his mouth without requiring them to be held. His pulse was stronger and temperature still normal.

Subcutaneous injections were given at 10.30 A. M. and 9.30 P. M.

November 18th, fifth day. There had been an intermission of fourteen and one half hours without convulsions, most of the time the patient sleeping quietly, but at two P. M. a series of very violent ones began, requiring morphine frequently. As the patient continually put his hands upon his abdomen, and some flatus was noticed, it was thought that an enema might produce a more comfortable condition, but no sooner was the tube inserted than there were convulsions of as severe a type as he had on the first night. The whole body would become rigid, then the head and knees would approach until nearly touching, when, suddenly, he would throw himself into complete opisthotonos, and lie so until the face became livid, when relaxation took place. There were four of these convulsions, with about two minutes' interval between before the subcutaneous injection, which was at once given, produced its effect.

After lying about two hours in a perfectly exhausted condition, his temperature meanwhile rising to 100.2° F., he began to talk with perfect distinctness. These were the first articulate sounds he had made since the commencement of his sickness. The words were perfectly intelligible and the sentences well arranged, but his ideas were all terrible delusions. He saw strange and frightful animals about, whose attacks he tried in vain to ward off, but they always bit his head; he was caught in the sands, and the tide was rising around him; his head was bound with hot irons, etc. He remained in this condition of delirium nearly all night, but as the morphine took effect his fancies became more pleasant. The head and limbs were in constant motion until he fell asleep, towards morning. Pulse 58.

Subcutaneous injections at 2, 4.15, 6.15, 9.30, and 11 P. M.

November 19th. When he awoke he was in the same lethargic condition as before the delirium, but this soon passed away, and his delusions returned; yielding, however, more readily to morphine. The temperature was 101° F.; pulse 60. There were no convulsions until evening, then but two slight ones, and he passed the night more quietly and naturally than any previous one.

Subcutaneous injections at 1.45 and 8 A. M., and at 8 P. M.

November 20th, seventh day. When he woke he recognized his relatives, who were in the room, but did not speak to them. He took full amounts of nourishment, and appeared perfectly conscious of his surroundings, dozing at intervals during the day. In the evening, without apparent cause, there was a very severe convulsion, after which the customary delirium. When asleep there was absence of those muscular twitchings which were present during most of the waking hours, and were especially induced by any excitement, however trivial, such as drinking, etc.

Subcutaneous injections at 3.15 and 11 P. M.

November 21st, eighth day. During the night he complained of pain in the front of the head, but said this had passed away in the morning. He was perfectly rational, knew and spoke to those about him, inquired the day of the week, and, when told, said, "I've been sick only a day then." He slept much during the day, but at night grew very restless. No morphine given.

November 22d, ninth day. Perfectly rational during the day. Micturition and defecation voluntary for the first time. Although perfectly quiet through the day, at night he was very restless. No morphine given.

November 23d. After a restless night the temperature was 103° F., pulse 90, and the general condition worse. The muscular twitching returned, and he lay in a lethargy so deep it was impossible at times to rouse him for nourishment.

Subcutaneous injections at 5.45 A. M. and 8 P. M.

November 24th. During the night the skin became moister, and he was greatly improved when he woke in the morning. The same condition of nervous excitement returned at night, although he slept a great deal during the day. Yawning was quite a noticeable symptom. Pulse was 78, temperature 100.4° F.

Subcutaneous injections at eight and eleven P. M.

November 25th. Complained of pain in the head, especially in front, and passed the day in the same somnolent state, growing restless towards evening. Epistaxis.

Subcutaneous injections at nine and ten P. M.

November 26th. Pulse 66, temperature 99° F. Epistaxis. Patient was very much improved, sleep was natural, and nourishment was taken freely. The history of succeeding days was that of steady convalescence, the only point of interest being the pulse, which remained below 60 for some time, and then gradually rose to its normal rate.

December 7th. Convalescence, beginning at the end of the second week, was interrupted in the middle of the fourth week, after the patient had been about the house for some days and out of doors once, by a return of convulsions, in a less severe form, accompanied by dilated and insensible pupils, and followed for two or three days by moderate fever, restlessness, and debility. The patient complained of renewed pain in the head, neck, abdomen, præcordia, and legs. The cervical muscles were contracted, there was intolerance of light, frequent spasmodic twitching of the face, lips, and arms, coated tongue, and a sluggish mental state as before, with active delirium at night. The subcutaneous injection of morphine was resumed, and the services of Dr. Strong were again needed for three nights, after which progress toward recovery was rapid. At the end of five weeks the headache had disappeared, but there was still some stiffness of the neck,

and after two months the patient was well enough to return to college.

Six weeks later he had a severe attack of diphtheria, involving the tonsils, soft palate, pharynx, and nostrils, attended by marked prostration. As neither of the above attacks could be traced to any local cause, it was thought that they indicated an unusual susceptibility to zymotic influences on the part of the patient.

CASE II. J. C., aged fourteen, school-boy, entered the City Hospital November 27, 1881. He had been taken two days before with headache, pain in the back and legs, and persistent vomiting. Tongue moist and coated. Bowels constipated. Pulse 99; temperature 101.6° F. An ice-cap was ordered. Cracked ice; milk and lime water; sponge bath. Ten grains of bromide of potassium were given every four hours. Bowels evacuated by enema. The night after entrance he became delirious, and on the next day the head was strongly retracted, with tenderness over spinous processes and hyperæsthesia of the extremities. The skin was cool, the face somewhat cyanotic, and an eruption of herpes appeared on the lips. Vomiting continued. Ptosis of right eyelids.

On the fourth day he was transferred to the care of Dr. Webber in the Department for Nervous and Renal Diseases. December 1st it was noted that attempts to straighten the head caused much pain, and that the skin was hot and dry. No *taches cérébrales*. The ice-bag was continued, with the use of ergot, morphine, and chloral.

During the second week the temperature, which had been as high as 105° F., remained at about 100° F., with a pulse of 60, strong and full. The pain diminished, but the head was still bent back and vomiting was frequent, so that small quantities only of milk and Mellin's food could be given, with stimulants. The mind was pretty clear.

In the third and fourth weeks the head was straighter, there was slight deafness, and complaint of pain in the neck and head. There was no recuperation, however; the stomach remained irritable; and the temperature was sub-normal most of the time, falling to 96.5° F. the day before death, which took place one month after entrance. There was no autopsy.

CASE III. J. H., laborer, aged twenty-four, was admitted to the hospital May 12, 1883, in wild delirium. The surface of the body was cool and bluish; head drawn back; eyelids closed; pupils contracted; tongue and lips dry, the former brown and cracked; sordes on teeth; jactitation of limbs; a few brown maculæ, apparently of recent origin, on shoulders and thighs. No rose spots; no œdema; no paralysis. The bladder extended nearly to the umbilicus and fifty-nine ounces of bloody urine were drawn by catheter, the patient becoming more tranquil afterward, and the next morning he had recovered consciousness. He then stated that for several days he had had a dull headache, and suddenly without warning fell down, remembering nothing afterward. At entrance the temperature was 102° F., pulse 100. Urine normal, with the exception of the blood. Catheterization was necessary for several days, during which he was roused with some difficulty, lying with the head thrown back and suffering pain in the neck when touched or moved. The temperature remained at 101° F., and the pulse at about 100, during the first week. An eruption of herpes appeared on the lips, and debility was great. Half an ounce of whiskey was given every hour for several days, with milk, and an ice-cap was in constant use. There was no vomiting, but constipation was marked.

In the second week after admission the pain disappeared, leaving no stiffness; the temperature was sub-normal, tongue clean; emaciation and weakness considerable. Convalescence slow, the patient remaining six weeks in hospital. In the treatment no drugs were used except morphine.

CASE IV. M. C., laborer, aged twenty-six, was admitted May 15, 1883, having suffered three days with pains in the head, neck, and extremities, constant nausea, occasional vomiting, nosebleed once or twice, insomnia, and constipation. At the time of entrance there was severe pain in the dorsal region of the spine, with constant groaning, the slightest movement causing intense suffering. Temperature 101° F.; pulse 84. A poultice was applied to the nape of the neck, ice-cap to the head, and large doses of morphine were given. The bowels were moved by calomel and enemata. The next day there was extreme spinal tenderness, retraction of the head, and herpes on the mouth and nose. For ten days the patient remained in a stupor, with temperature 103° F., pulse about 80. But the signs of pain gradually subsided, and on the eleventh day after admission he was comfortable, with a sudden fall of five degrees to the normal temperature, and a pulse of 70.

Convalescence was interrupted early in the fourth week by a recurrence of the spinal pains and stupor, which lasted two days, but after a month the patient could walk about, though there was considerable muscular stiffness.

CASE V. C. H., aged thirty-six, was brought into the hospital by the police September 25, 1883, in a semi-comatose condition. He had no friends, and no previous history could be obtained. His conjunctivæ were slightly congested; pupils equal; considerable apparent deafness; retention of urine, and mild delirium from the time of entrance until death. There was no paralysis of the extremities, no nausea or vomiting, and no muscular tremor. Fifty-one ounces of urine were withdrawn by catheter, and his bowels moved once. Temperature 102.6° F.; pulse 94.

September 26th. Last night he complained of considerable pain and was quite noisy. He took little nourishment, owing apparently to difficulty in swallowing. The urine was slightly high colored, strongly acid, of 1018 specific gravity, and contained a slight trace of albumen. Pulse very weak. Brandy was given subcutaneously.

September 27th. He gradually failed, and died this morning at 2.10, about thirty-six hours after entrance. Dr. George B. Shattuck, under whose care he was, gave me the above notes and the report of the autopsy.

Autopsy by Dr. Gannett (eighteen hours after death). Body of medium size and fairly well developed and nourished. Marked lividity of dependent portions. Rigor mortis present.

Brain. Nothing unusual about calvaria. Dura everywhere thin and translucent. Sinuses contained a moderate amount of coagulated blood; sulci of pia of convexities opaque and of a grayish-yellow color. Surface of convexities dry. Convolutions flattened. Pia at the base of brain along clivus and the under surface of cerebellum opaque and of a greenish-yellow color. On scraping with the knife, soft greenish-yellow masses could be removed. Vessels at the base and of the fissure of Sylvius showed nothing unusual. Lateral ven-

tricles distended three times their usual size, containing an opaque grayish fluid. Ependyma everywhere velvety, softened, opaque, and of a grayish tint. Velum interpositum reddened and injected. Fourth ventricle showed similar appearances. Section of the brain substance in general showed the puncta cruenta of normal size. Brain substance of normal consistency. Section of pons, medulla, and basal ganglion showed nothing of especial importance. Vessels of pia contained considerable blood.

Cord. Abundant escape of puriform fluid from submural space of the cord. Vessels of pia along surface of enlargements and along whole dorsal posterior region showed an abundant collection of greenish-yellow puriform fluid. Anterior region, same appearances of a less degree. Cord not opened; preserved.

Diaphragm. Right and left upper border of fourth rib.

Pericardium contained fifteen cubic centimetres clear fluid. Visceral surface of pericardium thickened and grayish in portions over anterior surfaces.

Heart somewhat enlarged in long diameter. Left ventricle very firmly contracted. Right ventricle and auricle distended with partly coagulated blood. Mitral valve admitted tips of three fingers; tricupsid tips of four. Valves and cavities not remarkable. Muscular substance of left ventricle increased one third in amount. Color and consistency good. Nothing remarkable about coronary arteries. Pleural surfaces of both sides free from adhesions.

Lungs partially contracted and everywhere crepitant, on section showed a rather pale red somewhat moist surface, and yielded on pressure a slight amount of pale fluid. Bronchi contained throughout a moderate amount of thick mucus. Bronchial mucous membrane showed nothing remarkable.

Spleen nearly double in size; usual color; somewhat diminished density. On section, pulp somewhat increased in amount and softer than normal.

Left kidney diminished one third in size; of a red color; density slightly increased; capsule detached with tolerable ease; external surface granular. On section, cortex somewhat diminished in size; of a grayish-red tint, and somewhat opaque. The distinction between convoluted and straight tubules not easily made out. Pyramids showed numerous gray lines parallel to course of tubules.

Right kidney slightly smaller than usual; had a few cysts size of large filberts beneath capsule with clear fluid contents. Otherwise kidney presented same appearances as described in the other. Œsophagus, stomach, intestines, and liver, not remarkable.

Diagnosis. Acute cerebro-spinal meningitis; acute ependymitis; acute hydrocephalus; chronic circumscribed pericarditis; hypertrophy of left ventricle of heart; acute hyperplasia of spleen; chronic interstitial nephritis (moderate degree) with cyst formation.

Remarks. In commenting on the above cases it may be said that all were severe, Cases I., II., and V. presenting many of the graver symptoms. All were adult males except the boy of fourteen. What the first case would have developed into in twelve or twenty-four hours if it had been left untreated it is impossible to say, but I thought at the time that the early evacuation of the stomach by apomorphia prevented exhausting vomiting, and that the anti-convulsive effect of morphine and atropine, with the use of nutritive and stimulating enemata during the period of unconsciousness, might have been the means of saving life. In epidemics, cases of the fulminating type rarely recover, the initial collapse usually becoming complete and death ensuing rapidly, sometimes in a few hours. Patients who survive the shock to the vital functions and live for a few days have a fair chance of recovery, a majority of fatal cases ending within five days.

Diagnosis. Hospital cases are seldom seen at the beginning of the attack. When they are brought in unconscious, as in Case V., an accurate history is not obtainable, and it is hardly possible during life to discriminate between the various causes of coma. The absence of paralysis, however, with normal or slightly albuminous urine, and the exclusion of hysteria, epilepsy, and poisoning, might, in times of epidemic, determine a probable diagnosis. The general appearance is not characteristic of typhoid, more so of typhus. In some epidemics of cerebro-spinal meningitis the petechial eruption, from which the synonym, spotted fever, is derived, is often seen, in others rarely. It was not present in any of the cases reported. The retracted head and hyperæsthesia of body and extremities due to the spinal meningitis are usually noticeable even in a state of partial coma. Herpes of the lips and face is of some value as a diagnostic sign. Certain cases of malignant or suppressed scarlet fever, so-called, fatal within twenty-four hours, may present much the same symptoms as those of the severest form of cerebro-spinal meningitis, and even an autopsy might not aid the diagnosis.

Symptoms. In these five cases retraction of the head with intense pain in the back of the neck, and prolonged headache with general hyperæsthesia, were the most noticeable indications of the disease, in all except the last, who entered the hospital moribund. Persistent vomiting, in Case II., seemed to be the main cause of exhaustion. In two other instances it was an early symptom. Constipation was present in every case; herpes of the lips and face in four; retention of urine in three, in one of whom it lasted a week; hæmaturia once, and a small amount of albumen twice; epistaxis in two cases; sore throat in one. The patients usually lay upon the side, as that position favors retraction of the head and relaxation of the cervical muscles.

The skin was dusky or cyanotic in most instances, the tongue dry and coated. There was in all more or less fever, the temperature rising to 105° F. in one case, but the height of the thermometer was not always proportionate to the severity of the symptoms, especially in Case I., whose axillary temperature was usually about 99° F., occasionally rising two or three degrees. In Case II. a sub-normal temperature and high pulse prevailed during the last week or more, the case ending fatally. The pulse generally ranged below 100, in two cases falling to 60.

Among the symptoms referable to the nervous system delirium, more or less prolonged, was noticed in every case, sometimes with subsultus and carphologia. Stupor, in varying degrees to complete coma, with hyperæsthesia, as before mentioned, usually coexisted. Convulsions occurred in one case. One patient had dilated and insensible pupils for a week; in another they were contracted. The conjunctivæ were congested in two cases. Deafness was observed twice; ptosis of the eyelid once. There was no other form of muscular paralysis, and this comparative immunity

among the subjects of cerebro-spinal meningitis has often been remarked.

Relapses or recurrence of symptoms, lasting a few days, happened twice in the third and fourth weeks. Muscular stiffness and debility in most instances lasted some time, and in one case there was effusion into the knee-joint, rapidly absorbed. Two cases were fatal. The death-rate in epidemics has varied from thirty-six to eighty per cent.

Pathology. The pathological appearances are well illustrated by the autopsy in Case V. The inflammation of the arachnoid and pia mater generally assumes a purulent form. In cases immediately fatal from shock and collapse, the anatomical evidence may be slight or wanting, although the brain is usually anæmic and œdematous. The ventricles are often found at a later stage distended with serum.

Treatment. In treating a self-limited disease of short duration with such a violent onset that the vital functions are often disabled at the start it is all-important to try to bridge over the few most critical days by artificial means. At the outset, if the stomach and bowels are full, it is well to empty them, and no emetic agent is so good as apomorphia, which may be used hypodermically in doses of one sixth to one tenth grain in adults, and one twentieth to one thirtieth in children. The sedative and relaxing effect of apomorphia is also very valuable in cases of convulsion, like Case I. A comatose condition or vomiting of cerebral origin would indicate the propriety of rectal alimentation. In many cases early blood-letting is advisable, and the utility of cold applications to the head and spine is generally conceded, although I could see no direct benefit from them in the cases reported, on the contrary, they were often uncomfortable.

Beyond this, symptomatic treatment is necessary, and chief among drugs is opium, supplemented, perhaps, by atropine and bromide of potassium during the acute stage of the disease; there is little fear of narcotism. Diuretic and diaphoretic measures are useful, especially the hot-air bath. Quinine and ergot, with iodide of potassium and mercury as absorbents of the effused product at a later stage, have been recommended, but in no disease is the "post ergo propter" mode of inference as applied to the effect of drugs more likely to be fallacious.

Causation unknown. Under the same sanitary conditions cerebro-spinal meningitis prevailed extensively in Boston in 1873, when there were 216 deaths as compared with sixty the year before, and thirty-five the year after, the violence of the influence appearing to exhaust itself in a single year. In 1872–1873 it went hand in hand with an extensive outbreak of scarlet fever, following closely or accompanying the end of the severest epidemic of small-pox that Boston has experienced since the introduction of vaccination, items which I quote from the late Dr. T. B. Curtis's valuable report on the Sanitary Condition of Boston, published in 1875. Of course those localities suffered most from these diseases where the worst sanitary conditions prevailed, and the victims were least able to withstand their ravages, but the surroundings play a less important part in the causation of cerebro-spinal meningitis than of other epidemic diseases. Winter and spring have been the seasons, and crowded barracks the favorite places for its attacks, excessive fatigue, insufficient food, and exposure to cold acting as predisposing causes. A few doubtful cases only of contagion have been reported. Robust males between fifteen and thirty-five are the usual subjects, although in children, among whom the disease has at times extensively prevailed, the disproportion between the sexes of the patients is not great. The occurrence of cerebro-spinal meningitis in animals has often been observed, especially among horses in New York for some months before the epidemic in 1872, which preceded the outbreak in this vicinity by about a year.

History. Although there is not time to enter at length upon the history of cerebro-spinal meningitis in New England the narrative is interesting, and brief mention may be made of the earliest epidemic in Massachusetts, in 1806, when nine cases occurred in the town of Medfield, all fatal; of the report on Spotted or Petechial Fever, in 1810, by Drs. Thomas Walsh, James Jackson, and John C. Warren, a committee of the Massachusetts Medical Society; of the report to this Society, by Dr. Joseph Sargent, of a limited epidemic in Worcester County in 1849; and again, in 1866, that of a committee of the Massachusetts Medical Society, who found that 280 cases had been recorded in the State during the previous nine years, with a mortality of sixty-one per cent.

Much of the earlier literature on this subject is French, and admirably presented since the beginning of this century. Great Britain, with the exception of Ireland, where one epidemic among the constabulary caused a mortality of eighty per cent., has been comparatively free from the disease, and in Germany it attracted little notice until about twenty years ago. In this country, however, no disease has been more carefully watched and recorded, and among the numerous publications of later years the Boylston Prize Essay for 1866, by Dr. Samuel G. Webber, is especially complete and suggestive. Dr. Webber called attention to the pneumonic form of the disease, in which the lungs bear the brunt of the attack, the cerebro-spinal symptoms being delayed or imperfectly developed. Such a class of cases, in which croupous pneumonia was complicated by cerebro-spinal meningitis, especially in children, was afterward described by Immermann, Heller, and other German writers. Dr. J. Lewis Smith, of New York, in commenting upon this type of disease, states that in the epidemic season of 1872 in that city an unusually large number of cases of pleuro-pneumonia of an asthenic kind occurred among old people, suggestive of a common atmospheric cause.

The monographs of Professor Stillé and of Dr. Meredith Clymer portrayed the disease as it appeared in Philadelphia and New York, and the Sanitary Memoirs of the War contain a valuable article by Dr. S. B. Hunt. The State Board of Health of Michigan published an excellent report by Dr. Henry B. Baker in 1874, and in the same year Dr. J. Baxter Upham, who had previously described the Epidemics in the Camps about Newbern, N. C., in 1863, wrote a very complete and interesting history of the epidemic of 1873 for the State Board of Health of Massachusetts, in which it appears that 517 cases were returned by 199 physicians, and that there were 216 deaths in Boston alone. Dr. Upham informs us that it was not until 1867 that "cerebro-spinal meningitis" appeared as such in the nomenclature of the city records, and not until 1872 in those of the State, cases of this disease having previously been classed with others under the head of "cephalitis."

During the decade 1873–1883 2053 deaths have oc-

curred from cerebro-spinal meningitis in Massachusetts, 747 of them in 1873 alone, leaving an average of 130 fatal cases for each of the other nine years. Suffolk County has returned 476 deaths, Middlesex 412, and Worcester 240, but there has been a steady though small rate of mortality from this cause in most of the cities and many country towns in all sections of the State except Cape Cod and the islands, where it has been trivial. For the last two or three years the number of deaths has increased moderately, namely, to 157 in 1881, and 166 in 1882, the distribution in 1881 being chiefly as follows: Middlesex County, 27; Suffolk, 24; Hampden, 21; Essex, 19; Worcester, 14.

The valuable Mortality Tables of the State Board of Health, published weekly in the JOURNAL, show that neither of the diseases mentioned above, smallpox, scarlet fever, and cerebro-spinal meningitis, has prevailed during these years to an alarming extent, the epidemic type having been mild, but the seed has still lingered in our midst, and is wide-spread, cases of cerebro-spinal meningitis cropping up from time to time among the susceptible in such a way as to suggest the probability of a future outbreak whenever the mysterious combination of influences occurs on which such visitations depend.

A CASE OF SUDDEN AMAUROSIS. RECOVERY.[1]

BY HASKET DERBY, M. D.

THE following case is both so unusual, as to occurrence, and so unexpected, as to result, that I have thought a brief report of even the scanty details I have at my command might not be without interest.

October 13, 1883, I saw Mary T., aged fifteen, for the first time. Near sighted since early childhood, she had grown steadily more so during her school life, and was using spectacles, right −9.5 D, left −8 D, all the time and for all purposes. A close, ambitious student, and attending a public school, she had worked unremittingly for the past year, making her studies her principal object in life, and paying little or no attention to her general health. This, however, had ordinarily been very good, with the exception of catamenial irregularity. The flow commenced at the age of thirteen, and had never been present oftener than once in two months. She was large for her age, and apparently neither nervous nor imaginative. Since the spring of this year she had, for the first time, been subject to severe headaches, not attended by nausea, extending over the whole head, lasting both day and night, materially worse during this fall. She came to me on account of failure of sight, which had been coming on for two weeks. Observing that her eyes were watering and her vision blurry, she had covered her left eye, and ascertained, to her astonishment, that she could not see with the right. Since making this discovery, a fortnight ago, the left eye had rapidly lost ground, and she was now unable to continue her studies.

The eyes were prominent and the pupils large, but presented no abnormal appearance to external inspection. Ophthalmoscopically there was a large, but defined and apparently non-progressive sclerotico-choroiditis posterior surrounding each optic entrance. The remaining fundus of each eye was entirely normal; no isolated patches of atrophy, no change in the circulation, no whiteness of the nerves. With 13 D concave the left eye had vision one tenth, the visual field being not contracted. *The right eye had no perception of light whatever*, either when tried by the mirror of the ophthalmoscope, by a lighted candle in a dark room, or exposed to the full glare of sunlight. The pupil of this eye was most active, contracting and expanding under light and shade, the other eye of course being closed.

What was the diagnosis? The first suspicion was naturally of malingering. The perfect honesty and simplicity of the patient went far towards removing this, and the usual tests with prisms showed the entire correctness of her statement. There were no other symptoms to encourage the diagnosis of hysterical amaurosis, no signs of general hysteria, of nervous derangement, of affections of other organs of special sense, or of local hyperæsthesia. All ophthalmoscopic indications were wanting. The ready response of the pupil to light and shade showed the deep-seated character of the affection, and that, according to Flourens, it must be located beyond the corpora quadrigemina; hence that it was likely to be diffused through a considerable portion of the brain. Such affections, says Leber, may occupy a region the integrity of which is essential to the maintenance of life itself. When the blindness is complete the general prognosis, according to him, is always grave. Should, in a short time, however, no affection of the general health occur, the chance of an ultimate restoration of sight is encouraging, the probability then being that there is no gross material lesion, but a local derangement that may readily disappear.

Four days later the condition of the patient was wholly unchanged. Entirely at a loss as to diagnosis, but in the hope that a possible derangement of the cerebral circulation might be connected both with the headache and the loss of sight, and if so, be affected by a local abstraction of blood, I applied the artificial leech to the right temple, removing an ounce and a half of blood. Lactate of zinc was also ordered in moderate doses.

The next day showed a result as remarkable as it was unexpected. The headache, which had been continuous and severe for six months, disappeared after the cupping, and has never since returned. Five days later there was distinct perception of light in the right eye, and even ability to follow the motions of the hand, held close to the eye. The cupping was now repeated, and again applied a week later. During this time each eye steadily gained. October 30th the right eye, armed with −12 D, had vision four tenths. The left, with −13 D, had two tenths. Each visual field could now be taken, and was found to be normal. November 6th there was

o. d. V 0.5 nearly.
o. s. V 0.4.

and this amount of vision continued when I last saw the patient, December 8th. In her own opinion her sight had fully returned. Her health was perfectly good, and she was wholly free from headache. Except for the high degree of myopia, and consequent imperfect vision, each eye seemed normal. She returned to school early in the present year.

None of the ordinary causes of cerebral amblyopia seem to have been active here. The termination of

[1] Read before the Ophthalmological Section of the Suffolk District Medical Society, January 29, 1884.

the case, of course, forbids the supposition of organic change at the base of the brain, of apoplexy, of a tumor, or of meningitis. There had been no suppression of urine. There was no suspicion of spinal disease. There had been, beyond the headache, no antecedent sickness. Finally, there was no ophthalmoscopic change, save the choroidal atrophy.

That the headache was in some way or other connected with the blindness seems probable, and that the sudden disappearance of the headache is due to the application of the Heurteloup cannot reasonably be doubted. This much-neglected instrument never entered into the armamentarium of the Vienna school of ophthalmology, much as its use was insisted on in Berlin. It is, I imagine, seldom if ever used by the majority of those here present. Of course it has no advantage over the old cupping apparatus, save in the greater facility of application to a region like the temple, particularly in the case of females. I think its disuse among ophthalmologists is seriously to be regretted. It was much employed and warmly advocated by Graefe, especially in cases of congestive amblyopia and chronic affections of the choroid; in fact, in all cases where a rapid evacuation of an appreciable amount of blood was indicated, but not, of course, in those forms of external ophthalmia where the prolonged and slow flowing of a steady stream is productive of decided benefit.

Local cupping has in our day seemed to share the fate of general venesection, a therapeutical method of value when judiciously used, greatly abused by routine practitioners, but whose total neglect is a distinct loss to medicine.

AN IMPROVED APPLIANCE IN THE PHYSIOLOGICAL TREATMENT OF CLEFT PALATE.[1]

BY HENRY A. BAKER, D. D. S.,
Lecturer on Oral Deformities, Boston Dental College.

It has usually been said that lesions of the palate arise from one of two causes, that is, they are either congenital or accidental.

Congenital cleft of the palate was as commonly treated surgically as by mechanism. The former treatment has been nearly or quite abandoned in recent years for two very good reasons: First, it is a very painful one for the patient, and difficult for the operator, and a failure of closure is largely in the majority. Second, it universally fails to improve the speech even after a successful closure.

Notwithstanding the above facts some physicians recommend staphyloraphy. They must certainly do so from want of knowledge of the anatomy and physiology of the vocal organs and their use in the mechanism of speech, which is the production of sound, and its direction through the nasal passage or the mouth at will, being controlled by certain organs whose modification and resonance enable us to form what we term articulate speech.

One of the most important aids in producing the above results is the soft palate. This organ is lifted up and comes in close contact with the pharyngeal wall, thus shutting off the nasal passage, which is absolutely essential in producing all excepting nasal sounds. After the operation of staphyloraphy such a closure is impossible, owing to the soft palate having been made too short and tense, hence defective speech invariably follows.

Accidental lesions of the palate, as the name suggests, are caused either by accident or disease. These cases may be successfully treated with a very simple appliance, while the same amount of skill exercised on a congenital cleft would have no beneficial result. This may be accounted for by the fact that in the former case the patient had learned to articulate distinctly, and use the organs of speech efficiently and correctly, while persons who are thus deformed from birth are obliged to learn the art and methods of articulation by slow and painful processes. The organs require the training which is necessary for one who acquires a new language. Hence the appliance for relief should not only fill up the gap in the defective palate, but should also be so constructed as to work on physiological principles in harmony with the natural movements; that is to say, it should be under perfect control of the surrounding muscles. It is manifest, therefore, that the success even of the most scientifically adjusted instrument depends largely upon the coöperation of the patient who uses it.

As the above malformations are classed as congenital, and accidental, the appliances for their relief are classed as follows: obturators and artificial vela. Among the former Dr. William Suersen is the inventor of one which has created much interest. The most important and significant advance in this department of science, however, made itself manifest in attempts to form an artificial velum, and Dr. Stearns was probably the first to introduce its true principle. I speak of these two investigators, Suersen and Stearns, because I am led to think that they have brought before the profession the most scientific apparatus of each class, and it is from a consideration of both of their appliances that I have evolved the principle, in explanation of which this paper has been prepared.

Suersen says: "In order to be able to pronounce all letters distinctly it is accordingly necessary to separate the cavity of the mouth from the cavity of the nose by means of muscular motion. That separation is, under normal conditions, effected, on the one hand, by the velum palati, which strains itself (consequently by the levator and tensor palati), but, on the other hand, also by a muscle, which to my knowledge has not yet received a sufficient amount of attention in connection with these operations. I mean the constrictor pharyngeus superior. This muscle contracts itself during the utterance of every letter pronounced without a nasal sound just as the levator palati does. The constrictor muscle contracts the cavum pharyngo-palatum, the pharyngeal wall bulging out, and it is chiefly on the action of this muscle that I base the system of my artificial palates."

It will be noticed that Suersen admits that the levator palati is an important organ of speech, yet he makes no provision for utilizing it as such, and only provides for the superior constrictor muscle coming in contact with the distal surface of his appliance to shut off the nasal passage. In my opinion, for the patient afflicted with congenital cleft to acquire perfect articulation with such an appliance (even if it be possible) years of application and training of this muscle would be necessary. A little reflection will show that this muscle, besides performing its own function, must be trained to fulfill those of the velum palati, levator palati, and

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, December 12, 1883.

tensor palati. But in an *accidental* lesion this may be all that is necessary, as the patient having previously learned to articulate distinctly, and having this deformity come upon him afterwards, the superior constrictor muscle would, no doubt, be sufficiently developed to perform that function.

Sir William Fergusson, in his report of a dissection made by him of a cleft palate in 1844, states distinctly that the superior constrictor was very full, and he also claimed for that muscle very decided forward action in deglutition. It was in the year 1841 and 1842 that Dr. Stearns made his first artificial velum. In 1860 Dr. N. W. Kingsley came into the field, and took up Dr. Stearns's appliance. Finding it too complicated for the general practitioner to construct, and too expensive when completed for those in ordinary circumstances, he was led to serious thought in regard to modifying its production, but he still adhered to the same principle of utilizing the levator muscle.

Dr. Kingsley says respecting Dr. Stearns's appliance: "Two principles were vital to Dr. Stearns's instrument, namely, first, the artificial velum should embrace the levator muscles of the palate, so that it could be lifted by them; and, second, that it should bridge the upper pharynx behind the uvula, and cut off nasal communication at will."

Dr. Kingsley's modification of Stearns's instrument consisted chiefly in leaving off the triple form, and doing away with the central slit, the flap, and the springs. The simplified form consisted of two leaves of soft vulcanized rubber, connected in the median line, the palatal portion running down to the uvula, and then bridging across at that point, and the nasal portion reaching across the pharynx. Instead of the appliance being made in sections so as to slide across each other, as in the Stearns, the bifurcated uvula slides between the two leaves, and the levator muscles of the palate lift it up to meet the pharynx, thus shutting off the nasal passage. It will be noticed that in this simplified form the Stearns principles are fully carried out, and to Dr. Kingsley that credit is due. His claims to originality are in the simplifying of the Stearns instrument.

Dr. Kingsley says: "An important principle enunciated by Dr. Stearns as essential to the success of all artificial vela for congenital cleft was that the instrument filling the fissure in the natural palate must be of the nature of a valve under the control of the muscles surrounding it, and so arranged that it could be elevated by them, thus shutting off the nasal passage, as is absolutely essential in the production of certain sounds belonging to articulate language. This principle was carried out by him first in the character of the material chosen, being of a yielding, elastic nature, and second in the form, being made to embrace the levator muscles, and subject to their control."

Dr. Kingsley in speaking of Suersen's appliance says: "First, that of all obturators this is the best form for a congenital fissure, but while the wearer is enabled to articulate with such an instrument it is only after he has learned articulation with another apparatus. Second, that a soft, elastic, artificial velum is much better adapted to the acquirement of articulation than any unyielding, non-elastic substance, but when acquired an obturator may be substituted. Third, that in very rare cases articulation may be acquired with an obturator only, but it is the result of the extra activity of the pharyngeal muscles, while with the elastic velum the levators of the palate contribute largely."

A great many practitioners in treating a fissured palate simply separate the nasal and buccal cavities by a thin plate, thinking that the separation is all that is required. Some even make a great parade of this device, claiming it to be an improvement over any other appliance. A little reflection will show this to be impossible, as I shall endeavor to explain before closing this paper.

My own experience with soft vulcanized rubber for an artificial velum is that if it would resist the fluids of the mouth, and not go through a process of decay, and change its form, in short, if it could be made permanent, it would be all that could be desired. Since this is impossible I do not hesitate to say that it is a very objectionable material, and I have been led to long and careful meditation regarding it.

I experimented for five years to provide an artificial appliance with hard rubber, carrying out the Stearns principle, whereby I could utilize the levator muscles to control the movement of the appliance, and with which articulation could be learned as well as with the soft rubber. My studies and experience induced me to settle upon the following device, which consists of a

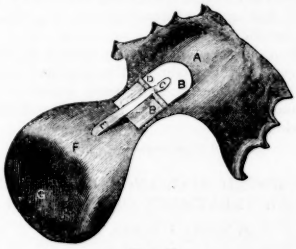

FIG. 1.[1]

gold or hard-rubber plate (A. Fig. 1), covering the roof of the mouth down to the junction of the hard and soft palates. From this point the artificial velum, F, extends back and downward, restoring the symmetry of the palatal surface by bridging across and lying upon the muscles of each side. The distal surface, G, or that portion coming in contact with the pharyngeal wall, is quite broad, and so constructed as to articulate perfectly with this surface, while the constrictor muscle contracts and closes around it on a semicircle. This is the Suersen principle, and the main ideas I take from that appliance.

The velum is of polished hard rubber, gold, or platinum, and much resembles a chestnut in form.

It is attached to the plate with a hinge joint, B, B, thus giving free movement at the junction of the hard and soft palate. At the junction of the hard and soft palate there is a stop, which prevents any downward pressure upon the muscles when in a relaxed condition.

The bulb-like form of the velum (see D, Fig. 4) necessitated a thickness which would naturally have made it quite heavy, and, as the resultant weight would be a serious objection, I was desirous of overcoming the difficulty. A suggestion happily came to

[1] The accompanying cuts are kindly loaned by Dr. J. W. White, the editor of the Dental Cosmos.

my relief in this way: While in a drug store I accidentally took up a hard rubber truss made by a Philadelphia firm. Discovering that the pad was made

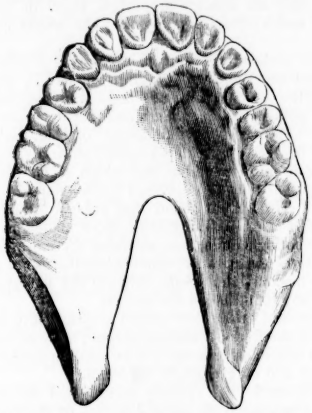

Fig. 2. The cleft, extending a little beyond the soft into the hard palate.

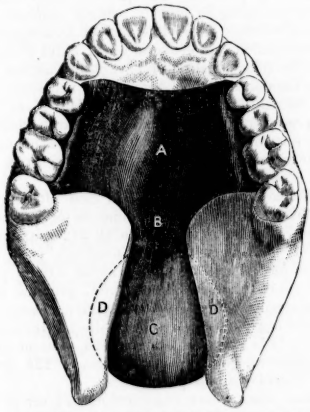

Fig. 3. Appliance in position: A, the plate; B, the stop, preventing any downward pressure when the muscles are in a relaxed condition; C, the artificial velum; D, D, muscle lying under it, the dotted lines showing the appliance resting on the muscles.

hollow, I thereupon wrote to the manufacturers, asking them if they would inform me how they prepared the rubber in that way. In their reply I found that the method was quite simple. It is as follows: Take the vulcanite rubber in the soft state and cut the sheets so that when joined together the desired form is given. Then a little water is dropped into the cavity (I found it better to add a little alcohol), the edges are sealed, and the piece vulcanized in the usual way. The steam produced by the water and alcohol inside creates sufficient pressure to keep the walls distended. By this method the appliance that the cuts were taken from which illustrate this article was made so light that it would not sink when put in water.

In treating a case by Kingsley's method I was obliged to use a hinge-joint to bridge over a union by staphyloraphy. I found in that case that the appliance was much better controlled by the surrounding muscles, and saw a much more rapid progress in acquiring articulate speech. This led me to more fully provide for that muscular movement, and I will endeavor to give the reasons why this should be done. As we have before quoted from Suersen, in order to pronounce all letters distinctly it is necessary to separate the cavity of the mouth from that of the nose by muscular action, and to close the nasal passage in pronouncing every letter, except *m* and *n*. This can be demonstrated by holding the nose while endeavoring to pronounce all the letters as plainly as possible.

In studying the mechanism of speech we learn that more than three fourths of the sounds of articulate language depend upon the integrity of the soft palate for their perfect enunciation. This being the fact, articulation with a rigid obturator must be extremely difficult to acquire. If three fourths of the sounds depend upon the free movement of the natural palate, it seems to me a sufficient reason why we should provide for that movement in an artificial one.

Dr. Kingsley says that with a yielding appliance the levators of the palate contribute largely to correct speech. The surrounding muscles have control over my appliance in the following way: The artificial velum bridges across the opening and lies upon the muscles of either side. (See Fig. 3, D, D.) With all sounds requiring the closure of the nasal passage it is thrown up (D, Fig. 4) by the levator muscles, there being no resistance. The thickness of the velum brings its posterior surface in close apposition with the superior constrictor muscle, F, and thereby affords, in the pronunciation of the gutturals, a firmer resistance to the pressure of the tongue, G, than can be obtained with a thin obturator. By the presence of the hinge, B, the above movements are rendered so free and easy

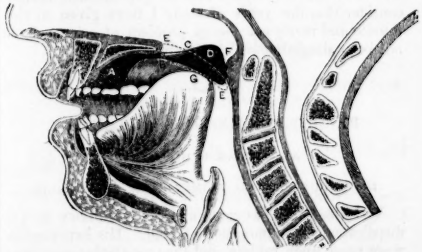

Fig. 4. The artificial palate thrown up by the muscles, E, E, as in all sounds requiring the closure of the nasal passage; F, the superior constrictor muscle advanced to meet it; G, the tongue, raised, pressing hard against the appliance, as in pronouncing the letter *k* or *g*; A, the plate; B, the hinge joint and stop.

that there is no tendency to any displacement of the plate, such as occurs with a rigid appliance. If a nasal sound immediately follows a guttural, the descent of the velum is rendered certain by its own weight. (Fig. 5, D.) My first instruments show a spring bridging over the hinge, by which I intended to accellerate the movements of the velum. This I found later to be unnecessary.

To accomplish the above with a material that would be permanent was a problem very difficult of solution. Of course it is impossible to give to a piece of mechanism muscular power, but it should be made so easily

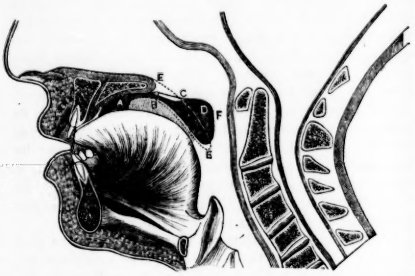

FIG. 5. The muscles relaxed, the appliance descended, thus giving a free passage for nasal sounds and respiration.

movable as to be acted upon by, and be under perfect control of, the muscles surrounding it.

I claim the following advantages for my appliance: —

First. That it is made of a permanent material.

Second. That articulation can be learned with it more readily than with any other appliance.

Third. That it is much easier to make.

Thus the unsatisfactory operation of the surgeon has been replaced by artificial organs of precision, working upon physiological principles. The ingenious appliances of our distinguished colleagues, Suersen, Stearns, and Kingsley, whose scientific attainments and researches have reflected such lustre upon the art of dental prosthesis, have excited my admiration as I have studied their complex operations; and if I have been enabled to extend their usefulness, and increase their value by substituting an imperishable material for the less excellent substances now in general use, I shall consider that the years of study I have given to this remote and rarely-considered problem of science have not been altogether without their reward.

REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M. D.

DISTRIBUTION AND ELIMINATION OF POISONS.

V. LEHMANN [1] has continued his researches on the distribution and elimination of lead. His experiments were made upon rabbits, and the preparation employed was plumbic nitrate, which was administered by subcutaneous injection in quantities varying from 0.016 to 0.500 gramme. The separation and quantitative determination of the lead were effected by electrolysis and the colorimetric method, using sulphuretted hydrogen in an alkaline solution. The results show that the liver, which in most cases of metallic poisoning holds the first place in order of examination, contains relatively to the weight very little lead. The bile, on the other hand, and the bones likewise, contain a large proportion. As much lead was found to be excreted in the fæces as in the urine; the lead thus excreted must have been eliminated in the bile, and not reabsorbed by the intestines, a circumstance which serves to explain the smaller proportion found in the liver, from which elimination by the bile would naturally occur.

The author investigated the changes which are brought about in the elimination of lead in the urine under the action of various therapeutic agents, especially potassic iodide. He found that the action of this salt is to promote the elimination of lead, exciting it, when this has ceased to take place naturally, by bringing again into circulation that which, so far as his investigations tend to show, had become deposited in the bones. He further found that potassic bromide, and probably also potassic chloride, have analogous effects in promoting elimination, and may therefore serve as substitutes for potassic iodide when the use of the latter is inadmissible. Sodic chloride did not appear to exert any influence on the process.

Guareschi [2] finds that arsenic is principally accumulated in the liver; a notable amount, however, is found in the lungs and kidneys, a very small quantity in the muscles and only traces in the brain.

C. Bischoff [3] has recently investigated the distribution of poisons in the various organs of the body, and has tried many of the methods recommended for the estimation of poisons. The present paper deals with cases of poisoning by phenol, potassic chlorate, oxalic acid, and potassic binoxalate, and by hydrocyanic acid, potassic cyanide, and essential oil of bitter almonds.

For the determination of phenol, the author recommends Landolt's method, but finds it necessary to continue the distillation until the distillate gives no further precipitate of tribromophenol on addition of bromine water. To isolate 0.5 gramme phenol from one kilogramme of substance about two litres of distillate is required.

In the case of a man who had died fifteen minutes after taking fifteen cubic centimetres of a ninety-one per cent. solution of carbolic acid, 242 grammes contents of stomach and small intestines gave 0.1711 gramme phenol; 112 grammes blood, 0.0259 gramme phenol; 1480 grammes liver, 0.637 gramme phenol; 322 grammes kidney, 0.201 gramme phenol; 508 grammes heart muscle, free from blood, 0.1866 gramme phenol; 1445 grammes brain, 0.314 gramme phenol; 420 grammes gluteal muscle, traces; 125 grammes urine, 0.0014 gramme phenol.

In two cases where putrefaction had set in before the post mortem either traces of phenol or none at all could be found in the organs.

Potassic chlorate is best estimated by dividing the dialysate from the organs into two parts, estimating the chlorine of the chlorides directly with silver solution in one, reducing the other with sulphurous acid, adding not too dilute nitric acid, and estimating the total chlorine as silver chloride. From the difference the chlorate can be calculated. Potassic chlorate is very soon reduced by moist organic substances, and especially by blood, so that chemical evidence may not be obtainable in undoubted cases of poisoning with potassic chlorate. Four cases were investigated in which death had followed the use of considerable quan-

tities of potassic chlorate for gargling, etc. In two cases not a trace could be detected; in one case traces were found; and in a fourth slight traces of chlorate could be isolated from the stomach and intestines, and their contents, but none from the liver, kidneys, or pancreas.

In cases of poisoning with oxalic acid or oxalates, quantitative estimation is essential on account of the wide diffusion of oxalic acid in the vegetable kingdom, and its consequent ingestion in food or medicine. Salt of sorrel consists more frequently of potassic tetroxalate than of dioxalate, and the tetroxalate on treatment with absolute alcohol is completely decomposed into free oxalic acid and insoluble dioxalate. On finding oxalic acid in an alcoholic extract, therefore, further experiments are needed to ascertain if the poison was oxalic acid or salt of sorrel. The organs are best extracted with alcohol, without addition of acid, to dissolve free oxalic acid and the "half bound" acid of tetroxalates, then digested with water to dissolve any alkaline oxalate, and finally with dilute hydrochloric acid to dissolve any calcic oxalate, the oxalic acid being estimated in each extract. The quantitative results in five cases of poisoning are given.

The best method for the quantitative estimation of hydrocyanic acid is to mix with excess of alcohol, acidulate with tartaric acid, and distill, a constant stream of air or carbonic anhydride being passed through the apparatus, and the distillate received into a concentrated solution of silver nitrate. The results obtained in five cases are tabulated. The contents of the stomach and intestines contained the largest amount; next in order was the blood. No hydrocyanic acid was found in the urine, and very minute quantities only or none could be found in the muscles.

ARSENIC.

Dr. D. W. Finlay [1] reports a case of poisoning in which death took place in one hour after swallowing a solution containing upwards of twenty-six grains arsenious oxide (white arsenic). This is, we believe, the shortest fatal period on record with one exception. Symptoms referable to the stomach were slight, but collapse was profound.

ON CHANGES IN THE CORD AFTER POISONING WITH ARSENIC, LEAD, AND MERCURY.

Dr. N. Popow [2] has studied the above subject experimentally. The results of his investigation are tabulated as follows: —

(1.) Arsenic, lead, and mercury produce marked changes in the cord in acute cases of poisoning, which must be regarded of the character of an acute central myelitis.

(2.) In relatively protracted cases these changes are not confined to the gray substance, but invade the white, and thus represent the form of a diffuse myelitis.

(3.) The peripheral nervous system remains entirely unchanged by the rapid action of these poisons.

(4.) The clinical symptoms on the part of the nervous system are fully explained by the changes described above, while no one of them can be explained by an affection of the peripheral nerves.

Popow's experiments were made chiefly upon dogs, and the doses were in most cases regulated, so as to contrast the results in both acute and chronic poisoning.

MODIFICATIONS OF GMELIN'S TEST FOR THE BILIARY PIGMENTS.[3]

Krehbiel adds to four parts of the urine to be tested one part hydrochloric acid, then drop by drop a saturated aqueous solution of chloride of lime. After the addition of three to six drops the characteristic green color appears, and is followed upon further addition of chloride of lime by the well-known play of colors.

Capranica recommends the following reaction as especially sensitive. The coloring matter is first extracted by shaking with ether or chloroform. To the solution thus obtained a five per cent. solution of bromine in alcohol is cautiously added until the green color appears. The coloring matter can now be completely removed from the ether or chloroform by shaking with hydrochloric acid. The green color is perceptible if the original solution contains no more than one part of coloring matter in two hundred thousand.

EXAMINATION OF URINARY SEDIMENTS.

Certain urines, especially concentrated urines and those passed in febrile conditions, deposit upon standing a considerable sediment composed chiefly of alkaline urates, and often deeply colored by uroerythrine. The detection of the organized sediments, such as blood globules, epithelium, casts, etc., in such cases is difficult and often impossible. To facilitate the examination in such cases Méhu [4] adds to such sediments, after they have subsided and after most of the urine has been removed, a small quantity of a saturated aqueous solution of ordinary sodic phosphate. This dissolves completely the pigments and urates so that the subsequent examination of the sediment is comparatively easy. An excess of the sodic phosphate does no harm, but its addition frequently causes a precipitation of crystalline calcic phosphate. Méhu prefers this method of treatment to the common one in which the urates are dissolved with water. The latter delays the subsidence of the organized elements, and besides tends to soften and break them up.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

January 28, 1884. Dr. Charles D. Homans presided.

COLLOID CANCER OF THE APPENDIX VERMIFORMIS.

Dr. F. W. Draper presented a specimen of colloid disease of the appendix cæci, and related the history of the case as follows: —

The patient was a man, sixty-five years old, a cooper by occupation. He used liquor moderately. He was always healthy until three months ago, when he had diarrhœa with alternations of constipation. Three weeks before his death vomiting first supervened, initiated by griping pain above the umbilicus. Everything ingested was almost immediately returned unchanged. There was no pain about the lower parts of the abdomen or about either iliac fossa.

The patient entered the City Hospital January 14th, and died January 18th. During this interval some

temporary relief was obtained for the obstinate vomiting by the use of morphia, dilute hydrocyanic acid, and champagne. The matter vomited consisted of mucus mingled with undigested milk-curds. There was moderate pain or "soreness" along the course of the transverse colon, but no tenderness in any part of the belly. The dejections were loose, dark-colored, or greenish, but the diarrhœa was less troublesome than the vomiting. Emaciation and weakness were marked. The temperature was 99.2° F.; the pulse varied but little from 100. Careful physical examination failed to detect any tumor or other local alteration to aid in establishing a diagnosis. The urine was normal in its chemical and microscopical characters. Obstinate hiccough occurred on the day before death, and aided the vomiting and diarrhœa in determining fatal exhaustion.

The autopsy found the specimen exhibited to the Society to be the only morbid part having relation to the cause of the death. The ileum immediately above the ileo-cæcal valve and for some distance along its course was dilated and distended with liquid fæcal matter. Just at the valve, upon its upper side, three foreign bodies — two small fragments of bone and a prune stone — were found lying loosely before the orifice into the cæcum. The valve itself was constricted so as to admit with difficulty the tip of the forefinger. The mucous membrane of the cæcum and lower part of the ascending colon was thickened and deeply reddened, but not ulcerated. The upper third or head of the appendix was enlarged and dilated to such a degree that externally it was of the size and shape of a large plum; its cavity, deeply injected, was irregular in its surface, and would admit the little finger. The opening to the intestine from the appendix was also dilated. The thickened wall of this enlargement presented the characteristic appearances of colloid disease. The free end of the appendix beyond the dilated portion was very slightly enlarged, and contained inspissated fæcal matter in its canal. The peritonæum and sub-peritoneal tissues adjacent to the new growth were normal in appearance.

DR. W. W. GANNETT, in answer to a question, quoted Recklinghausen, that during his fifteen years' service at Wurzburg gall-stones and cancer of the gall-bladder were both rare. In his later service at Strasburg he found them both much more common. He did not advance this as absolute proof of the effect of mechanical irritation in producing malignant disease.

MALFORMATION OF THE VAGINA SIMULATING EXTROPHY OF THE BLADDER. LOBAR PNEUMONIA IN A YOUNG CHILD.

DR. T. M. ROTCH showed the specimen, and said that it had been seen by many physicians during life at the West End Dispensary, and had been taken by all of them for extrophy of the bladder. There was a large abdominal hernia, and below it a mucous surface that had been taken for the posterior wall of the bladder. On this surface were two culs-de-sac, which from their position had been taken for ureters. Still below and in the median line was a large orifice resembling the meatus of the urethra. A dissection by Dr. Whitney showed this to be the vagina, a probe passed outward from the uterus coming through it. The supposed ureters were culs-de-sac. Below them were two hitherto undiscovered orifices, the right of which was a blind opening, the left being the real urethra, as water flowed out through it when injected through either of the real ureters. By following down the ureters a normal bladder was found, through which the water passed. The exposed mucous surface was, therefore, a malformation of the vagina. The case was also interesting as dying from lobar pneumonia after an illness of twenty-four hours, beginning in the third day of life; young children having commonly lobular, catarrhal rather than lobar, fibrinous pneumonia. The left scapula was drawn up to the neck and attached to the upper rib.

CHRONIC NASAL CATARRH; REMOVAL OF HYPERTROPHIED TISSUE.

DR. F. I. KNIGHT showed two specimens removed by an operation which he has reason to think is not generally known except to specialists, and which gives much relief in some cases. The adenoid tissue of the vault of the pharynx and its posterior wall, resembling the tonsil, and sometimes called a "third tonsil," is capable of being much hypertrophied, and *may* block the nares, thus hurting the voice, and keeping up catarrh by compelling the patient to breathe through the mouth. This has been removed by twisting it off with forceps, which, if the tissue is hard, may do injury; or by burning it with galvano-forceps, which last is very dangerous if done carelessly, because it may set up inflammation in the middle ear. The speaker did not mean that the galvano-cautery has no place. It may be used with care in cauterizing a stump. The specimen presented had been removed by a snare. The other specimen was of the mucous membrane and submucous tissue (erectile tissue of Bigelow) covering the turbinated bones. This when hypertrophied does the same mischief as the large "third tonsil." Touching it with nitric acid is of no use. A weak snare may snap, but No. 5 piano wire, proposed by Jarvis, of New York, cuts through anything. It is placed through the nostril with the aid of the rhinoscope, and at least two hours must be used in cutting through or there may be serious hæmorrhage. The patient holds the instrument, and has pain only when the screw is tightening. He should be warned not to blow his nose for some hours.

DR. A. L. MASON read a paper on

CEREBRO-SPINAL MENINGITIS. FIVE CASES. — ONE OF THE FULMINANT TYPE, TREATED WITH APOMORPHIA, MORPHIA, AND ATROPIA. RECOVERY. — ONE AUTOPSY.[1]

DR. S. G. WEBBER said that he had been much interested in the paper, especially in the first case, which was rather anomalous. As the reader states, the causes linger after an epidemic, and now and then break out in sporadic cases. Such cases have occurred at Vienna since the last epidemic there. The speaker had himself seen a case in a neighboring town in which the symptoms developed ten days after a blow from a school teacher. This had been at first supposed to be their cause, but the disease was later seen to be cerebro-spinal meningitis, and this was confirmed by autopsy.

DR. J. J. PUTNAM referred to cases which have been reported (including one by Dr. Webber) in which the naked eye appearances of the membranes in undoubted cases of cerebro-spinal meningitis were negative, and also to the fact that spasms may be absent, or nearly so, throughout the sickness. Cases of this kind

[1] See page 125 of this number of the JOURNAL.

resemble in many respects severe cases of diffused neuritis.

Dr. Putnam also said that he had seen several children suffering with the sequelæ of cerebro-spinal meningitis, and that they were sometimes characterized by a peculiar oscillatory trembling of the hands, and sometimes localized atrophy of muscles.

Dr. Mason, in reply to Dr. Putnam's question as to the probable cause of death at a very early period in the disease, said that he supposed the fatal result might be due to shock. In cases fatal within a few hours, where the patients are struck down as if by lightning, the toxic influence is so powerful that the vital organs may cease to perform their functions before the anatomical changes in the nervous centres have developed. Sometimes, under such circumstances, the brain has been found to be anæmic and œdematous.

Dr. C. E. Stedman said that the different symptoms of the disease were illustrated by (1) a boy of eight years old who came home from school, and went out to play in apparent health; in the door-yard he had a fit, in which he died before Dr. Stedman could reach him, though answering the summons at once. The autopsy, in which Dr. Edes assisted, revealed cerebro-spinal meningitis, with deposits of pus. On the other hand, (2) a child, aged three, had cerebro-spinal meningitis, and was unconscious three weeks, taking little food and no medicine; at the end of that time he woke, was rational, called for his toys, and recovered. In regard to the connection between this disease and pneumonia, Immerman and Heller write of the Erlangen epidemic, that in fifteen cases meningitis complicated croupous pneumonia fourteen times and scarlatinal nephritis once. Dr. Stedman found one morning, in making his visit at the City Hospital, a man of sixty-five, unknown and unconscious, whom he recognized as a nurse. He died in a few hours, comatose, with paralysis of the left arm and ptosis of right eyelid. Autopsy showed cerebro-spinal meningitis. His former physician reported that he had just attended him through an attack of pneumonia, and in recalling the case, after the result of the autopsy was told him, he could recollect no symptom pointing to the brain or cord. The autopsy also illustrated the correctness of the diagnosis of pneumonia.

Dr. R. H. Fitz thought that the first in the series of cases reported was particularly interesting from the anomalous character of its symptoms. The course of the disease was so irregular that a certain doubt as to the exact nature of the process readily suggested itself. The low range of temperature in particular, in a disease whose synonym is "spotted fever," seemed especially noteworthy. If he had understood aright the temperature in general was in the vicinity of 99° F., exceeding this limit only in a single instance, somewhat late in the course of the disease. Although an atypical range of temperature was an important feature in the differential diagnosis between cerebro-spinal meningitis and other protracted febrile diseases, as typhus and typhoid fevers, the lack of type in the present instance seemed exceptionally characterized.

During the epidemic of 1873 Dr. Fitz had made numerous post-mortem examinations of cases of this disease, including those terminating fatally within ten hours from the beginning of the attack and those lingering for several weeks, if not months. The anatomical evidences of meningitis were always present, though in the extreme instances the macroscopic changes were far from being characteristic. A cellular infiltration of the pia mater was found in the fulminant cases, and the remains of the inflammatory product were seen in patients whose disease was continued throughout weeks and months. The extension of the inflammatory process into the cerebral ventricles, with the associated hydrocephalus, sometimes extreme, seemed of importance in explanation of the suddenness of death in certain cases, especially in those whose termination was rapidly fatal. A paralysis of respiration or an insufficiency of the heart might be regarded as the direct result of the greatly increased intracranial pressure, manifested not only by the obliterated furrows, flattened convolutions, and the anæmic brain, but also by the widely distended ventricles.

The reference made by Dr. Webber to the medico-legal importance of the recognition of cases of cerebro-spinal meningitis reminded Dr. Fitz of an analogous experience. During the late epidemic a young man was thrown to the ground in a drunken quarrel, his head striking a curb-stone. Death followed in the course of a few days, and evidences of a severe cerebro-spinal meningitis, without fracture of the skull, were found at the autopsy, which was made at the instance of the coroner. The question raised at the time concerned the relation between the violence and the lesions. It was concluded that the latter might have arisen independently of the violence, owing to the existing epidemic. The possibility of the lesions being excited by the blow could not be eliminated, although this alternative was regarded as less probable than the former in virtue of the appearances and the collateral circumstances.

Dr. Mason, in reply to Dr. Fitz's suggestion that Case I. was so anomalous in symptoms, especially in the low range of temperature, that the diagnosis might be questionable, said that it was not more so than many cases he had met with in the literature of the subject; that the best authorities called attention to the very great variety in temperatures or symptoms observed, so that so far no one who had not seen a large number of cases could be familiar with all the types. Cases with considerable depression might present a sub-normal temperature, as in Case II., but the axillary temperature is often a poor guide.

In Case I. Dr. Mason, after very careful observation in consultation with others, could find no more probable explanation of the symptoms, although he would be glad to have one suggested. The patient evidently had meningitis. Syphilis and tubercle could be fairly excluded, as the recovery was complete; and a simple idiopathic cerebro-spinal meningitis, if there is such an affection, must be very rare and undistinguishable from the disease in question.

Dr. C. F. Folsom said that in 1873 he had seen a case quite similar to the first of the five reported by the reader. The period of unconsciousness was somewhat longer, and the duration of the illness considerably longer, than in Dr. Mason's case. The patient was not able to resume his occupation until six months after his attack. The temperature was low, seldom going above 101° F.

Dr. Webber said, with reference to the point raised by Dr. Putnam, that during the epidemic of 1873 he had made an autopsy, in which, although no pus was seen by the naked eye, yet that microscopic sections had shown pus cells under the pia mater and in the substance of the cord.

The speaker had known total deafness to result from

an attack, and to remain unrelieved after six or eight years, notwithstanding much treatment from both physicians and quacks. He does not suppose this to be from a lesion of a nerve, but from disorganization of the labyrinth from infiltration of pus cells.

The symptoms vary as the brain or the cord is the principal seat of disease. He can well understand that, with cerebral lesions predominating, the temperature may be low. With regard to treatment, he recalls a case in which iodide of potassium was used with apparent good results. He does not remember whether ergot was used in the case or not. In simple cerebral meningitis iodide of potassium is of value, but it must be used in large doses, twenty or thirty grains four or five times a day.

DR. J. O. GREEN said that all the cases so far analyzed are insufficient to show the different conditions of deafness. They are not always the same.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.[1]

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

THE TREATMENT OF CLEFT PALATE.

DR. H. A. BAKER by invitation exhibited a patient for whom he had contrived an improved appliance for cleft palate, which is described on page 127 of this journal.

DR. HENRY J. BIGELOW remarked that he had been asked to say something upon this subject. It is quite exceptional that staphyloraphy alone without an obturator does much service to the speech. It is not difficult to get a union of the fissure, or of most of it, but the flaps are usually so tense afterward from the contraction of the dissected surfaces behind the palate that the play of the palate necessary to articulation is prevented. I have, therefore, usually recommended patients to get one of the varieties of artificial palate or obturator, whether inflexible like Suersen's, or flexible like Kingsley's, and to submit only to so much operation as may be necessary to keep it in place. After an operation patients expect to talk at once, but they cannot do so. A long education is needed to show any considerable improvement in alternating the mute and nasal consonants. As a rule there is no improvement of speech at first. Fifteen years ago I devised a short series of exercises in articulation for a patient I operated upon. It begins with the only consonant which a patient can usually best articulate, namely, "*t*" in "*tar*," and gradually leads to the rest, constantly referring to the acquired "*t*" as a point of departure. Here it is, as it was then printed for the private use of a patient: —

"The great difficulty in pronouncing correctly with a cleft palate is in distinguishing the nasals from the mutes; thus, p and b from m; pap or bab from mam; t and d from n; tat from nan; k and g (hard) from ng.

"'Tar' is well pronounced by most beginners with an obturator. When the beginner can pronounce 'stark' and 'car' he has the key to most of what here follows. The above words should be practiced carefully; not 'start' and 'tar,' but 'stark' and 'car,' and should be spoken loudly, or, as the elocutionists say, 'exploded.'

[1] Concluded from page 104.

1.	tar	artar	kar	arkar	kar
2.	kar	arkar	arkgar	kgar	gar
3.	kar	arkar	arkdar	kdar	dar
4.	kar	arkar	arkpar	kpar	par
5.	kar	arkar	arkbar	kbar	bar
6.	kar	arkar	arklar	klar	lar
7.	kar	arkar	arksar	ksar	sar

Practice all the above with the following vowels: —

8. o as in coke.

Thus, instead of kar, akar, etc., ko — oko — oklo — klo — lo

9. a (long) as in cake.
10. i as in kite.
11. e as in keep.
12. u as in suit.

13.	kar	arkar	arngar	arkar	arngar	kar	ngar
14.	tar	artar	arnar	artar	arnar	tar	nar
15.	par	arpar	armar	arpar	armar	par	mar
						bar	mar
						dar	mar
						sar	rar

(Practice reading loudly from a book.)
"*February*, 1870."

DR. GEORGE F. GRANT spoke as follows: In the physiological treatment of cleft palate there are many points which require the most careful consideration. I have listened to the paper of Dr. Baker with great interest because the subject is one to which I have devoted much time and attention, and during the past fourteen years have treated over seventy cases of congenital cleft palate. While I may claim to have succeeded in almost every case in securing a good articulation there have been great variations in the degree of success as well as in the length of time which is required for the patient to master the art of distinct articulation and enunciation.

At the commencement I made the mistake of expecting too much from the appliance unaided by proper direction to the patient in its use, that is to say, after adjusting the palate it was my practice to give the patient an exercise in sounds simply requesting him to follow me in their pronunciation. This plan did not prove satisfactory in all cases, and I now often wonder how so many did so well under so imperfect a system of training.

It soon became plain to me that patients of this class required to be taught the art of correct articulation technically, just as we are taught any other art which depends upon accurate technique. This fact applies also to the sister art of enunciation, and although there is quite a wide difference between these two factors of speech they are so closely allied in this particular branch of study that they may be considered as one in speaking of them in this relation.

I found that this class of patients is almost universally deficient in the management of the breath; that in the use of the voice they speak directly from the lungs without any check at the larynx as is the case in normal speech, and where this fault does not exist they attempt the closing of the nose by using the depressor muscles of that organ and disfigure the face greatly thereby.

While this fault exists, the development of correct habits of speech is impossible; for many, if not all the sounds of the language require for their proper enunciation that the air column be under the most perfect control. For example, most patients are quite unable to give the sounds of those letters which are classed as labials, with any force whatever after being taught the method, simply because they do not have the power

of sustaining a sufficient pressure of air. The proper thing to do is first to teach them to control the breath. It is best to give them a tube of some description, and teach them to blow through one end while the other end is immersed in water; the bubbles which arise are a good indication of the progress which is being made. They are then taught to check the air in the throat by the tongue, and by distending the cheeks make a reservoir of the mouth which furnishes air to the tube while the lungs are being filled through the nostrils so that a continuous stream of air passes through the tube. This, many of you will recognize as the method of using the blow-pipe, familiar to chemists and artisans. I know of no plan which so rapidly gives the patient that control of the breath so necessary to the first steps in articulation. This practice gives tone and strength to the lips and cheeks, the muscles of which I have observed to be much weaker than in persons of normal formation. I have seen many patients who could apparently distend the cheeks as well as any one, when in reality there was little or no pressure upon the inside, and the act was a fictitious one, as the cheeks would not sustain percussion.

After I have taught a patient to direct a column of air through the lips and to control its passage, it is much easier to instruct him in applying those modifications to the air current which constitute articulate speech. These modifications are taught singly, and the proper position and conditions of the organs employed in the production of a sound are ocularly demonstrated, first, because the patient can more quickly understand what he can *see;* secondly, because it is of great importance that the best skill should assist in developing the work which the appliance is designed to accomplish.

I have only time to say that this plan or system which has been slowly and practically developed, has for its basis the reduction (by analysis) of speech to its simplest mechanical principles, and no effort has been spared to bring the mastery of those principles within reach of the most ordinary intelligence. I do not agree with much that has been written and said regarding the classification of the sounds in the language. But I have one remark to make regarding the most common error, which, as I believe, can be shown by a little reflection. It is a common belief that patients of this class must struggle with the consonants, while the fact is that with a few exceptions the vowel sounds are much the most difficult to teach them, because the vowels are more dependent upon the quality of the voice as a whole than upon any position or local arrangement of the organs of speech; consequently a patient may be technically correct as to articulation and have a most unpleasant enunciation, due entirely to faulty location of the vowel sounds. That is, a patient may be able to give the sounds of simple single letters or elements, and yet be unable to converse or read distinctly because the voice has not received attention.

Few of these patients have made use of the anterior portion of the mouth in their efforts to articulate. Their whole mechanism has been misdirected to an almost vertical line with the larynx, so that if the same line were followed with a normal palate the voice would pass through the nares behind the palate instead of being thrown upon the anterior portion of the soft palate and the whole of the hard palate, and thence by reflection through the lips, as should be the case.

If you have followed me to this point you will observe that I have first taught the patient that he must have the air to make the sounds under his control; secondly, he has been taught how to employ it in conjunction with the organs of speech in forming the parts of speech; now it remains to show him where to put it. We all agree that those sounds, or tones rather, which have the best penetrative power and are most clearly enunciated have a high or sharp pitch; then the next thing to consider is how is it produced. Why are some men's voices so much clearer in tone than others? Some of it is due no doubt to anatomical causes, — the height of the dome of the palate for instance. But still there are physiological reasons. The man who enunciates best, and whose voice has purity and clearness of tone, makes it better still by careful study and training. He brings the focus as far forward upon the palate as it is possible to do; the sound wave from the larynx is projected as far upon the anterior portion of the palate as possible by holding the head in an erect position and opening the throat, bringing the tongue forward. It is this very point which it is important to impart to a cleft palate patient, and which it is necessary for him to master in order to complete the work which an artificial palate makes possible.

No enunciation is good without it; no articulation can be secured which will repay the trouble unless careful attention is given to these points, and I have seen so much accomplished by these methods that it seems almost a possible thing to train a patient into a fair articulation without any appliance. Two quite remarkable cases have come under my notice. In both the fissure was quite large, in one patient extending through the soft palate, in the other through the soft and half way through the hard palate. In both cases the articulation was remarkably good, and either by accident or training the method in one was almost faultless, so that I advised the patient to let well enough alone.

A word about appliances. Dr. Baker's appliance seems to me to be the addition of a hinge to a modification of the Suersen obturator, made by Dr. Kingsley, of New York. The original Suersen obturator was a solid bulb of hard rubber, so shaped as to retain contact with the divided palate under all conditions, and at the same time close the opening into the nares by the contact with the superior constrictor of the pharynx. Dr. Kingsley's improvement consisted in making the bulb hollow and placing it so as to slide upon a bar until the most effective position was determined, and then securing it in the desired position. The method of making the bulb hollow, and the conclusions at which he arrived regarding the comparative value of the Suersen and Kingsley systems, may be found in the book on Oral Deformities by Norman W. Kingsley.

Dr. Kingsley is of the opinion that a soft rubber appliance is best to acquire articulation with, while the hard rubber might be inserted with good results after articulation has been acquired, and I coincide with that view; for when a case of cleft palate has been brought to a successful result, and the palate is then removed, the patient is in a position analogous to perforate palate.

The articulation exists and only requires mechanical aid, so that whatever meets that requirement suffices.

There are objections to soft rubber as a material, but it has proved of too much benefit as an aid in giving

the best results in acquiring good articulation, and in that respect surpasses anything which I have seen. I do not think Dr. Baker did it justice in his remarks upon it; for he must have known that if it was properly made the die in which it was made was a permanent mould which rendered the vela capable of easy and limitless duplication, and so easy of adjustment that it could be sent to any part of the world, or, if necessary, made or duplicated by any dentist who would follow the directions which accompany it.

The cleanliness depends upon the individual, as does the cleanliness of anything worn about the person.

The best results are dependent solely upon skillful manipulation, and no appliance can be successfully adapted by an unskilled hand. There can be no fixed rule to follow; each case presents new features, which must be met as they appear. My preference is for the soft rubber, because it more readily fulfills the requirements, and because it has done better work than any appliance which I have yet seen, though I have seen a few cases in which the hard rubber obturator had proved very beneficial.

I will not intrude further upon your time than to say that one of my greatest complaints against the Suersen principle has been that it seems almost impossible to obtain a clear voice with it, a fact which I have attributed to its thickness obstructing the posterior portion of the nares, and in Dr. Baker's appliance I cannot see that the hinge obviates that difficulty.

The patient was then introduced, and the appliance could be seen in the mouth, and, by causing him to swallow, the relation of the instrument to the wall of the pharynx and to the alæ of the velum palati could be easily observed. It was evident that in the act of deglutition no communication between the nasal cavity and the pharynx existed, the posterior part of the obturator being raised up by the superior constrictor muscle of the pharynx, and pressed firmly against the posterior wall of the pharynx at the line of the naso-pharyngeal junction. The patient now removed the appliance, when an enormous fissure was disclosed, extending from a point near the incisor teeth through the entire hard palate and velum. Upon being asked to read, it was quite impossible to understand what the patient was saying. After replacing the appliance the same sentences were read, and every word was spoken with great distinctness, and could be easily understood by every person present. After this the patient was asked to read some new selection, and opening a book at random, commenced as follows: "Physicians generally agree that the moderate use of wine is beneficial." At this point the audience, pleased with the improvement in speech, and possibly desiring to express approbation of what was read, burst into applause, and appeared to be perfectly satisfied as to the usefulness of this instrument in cases of cleft palate. The patient remarked that he found the greatest comfort and solace in the fact that with the appliance in his mouth he was able to smoke, while without it he could not draw the vapor of the tobacco from the pipe into the mouth. With it, also, he can whistle, which he cannot do without it.

On motion of DR. MARCY it was voted that the thanks of the Section be rendered Dr. Baker for his important communication of original studies upon a most difficult subject and demonstration of ingenious mechanical appliances for the remedy of cleft palate.

On motion of DR. PRINCE a vote of thanks was tendered to the retiring chairman, DR. GEORGE B. SHATTUCK, for the zeal and fidelity with which he has conducted the deliberations of the Section during the past two years.

Adjourned at eleven o'clock.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, M. D., RECORDER.

THURSDAY evening, January 10, 1884. The President, DR. TYSON, in the chair.

OSTEO-MYELITIS OF TIBIA.

Exhibited by DR. C. M. WILSON.

G. L., aged forty-two, was admitted into the surgical ward of the Pennsylvania Hospital November 26, 1883. Sixteen days previously he had been knocked down on shipboard, and had sustained a wedge-shaped fracture of the tibia and an oblique fracture of the fibula of the right leg about the middle. When admitted the fragments were in malposition and partially united. There was considerable deformity, the lower fragment of the tibia being tilted up and overlapping the upper fragment. By appropriate treatment the fracture was retained in fairly good position, and the case was progressing favorably until the afternoon of December 26th, just one month after admission, when he had a severe chill, followed by a temperature of 103.5° F. He complained of violent pain in left shoulder-joint. He was treated with salicylate of sodium. Next morning his temperature was 102.5° F., with intense pain in both shoulders and elbows. The same anti-rheumatic treatment was continued under the supposition that the case was one of acute articular rheumatism, the man having been exposed to a draught. The afternoon of second day he had a severe chill, with an evening temperature of 104.4° F., and a presystolic mitral murmur was detected. Dr. Wilson now considered the case to be one of pyæmia, and gave massive doses of quinia, stimuli, and digitalis. The man steadily grew worse, and died of exhaustion on the morning of December 30th.

Post mortem twenty-six hours after death. Rigor mortis marked. Body well nourished. Posterior portion of body much discolored; extensive ecchymoses over arms and shoulders. Smaller patches over abdomen and chest. One and one half ounces of clear serum in the pericardial sac, with many ecchymoses over the surface of the heart. Both sides of heart relaxed and partially filled with post-mortem clots. The valves on right side appeared normal. The aortic valves were incompetent, and their free borders were roughened by recent vegetation. There was also some slight thickening and contraction. The mitral valves showed old thickening as well as signs of recent inflammation. The endocardium of the left ventricle showed numerous spots of ecchymoses. The heart weighed sixteen ounces, and its tissue was a good deal softened. Spleen normal. Left kidney weighed seven ounces, was somewhat swollen, and its tissues were slightly flabby. The capsule was thickened and somewhat adherent. The organ was congested and somewhat swollen. Right kidney weighed six ounces, and presented the same appearances as the left. Liver was large, swollen, and marked by the ribs. Its surface

was mottled with rounded yellowish patches surrounded by dark-red areolæ. Section showed it to be markedly congested. Its weight was four pounds four ounces. Lungs much congested. The base of the left being anteriorly bound down by old adhesions. The brain was not examined. Examination of the fracture showed it to be ununited, and there was no callus detectable. The periosteum tore easily. On section the medullary cavity of the tibia showed marked evidences of inflammation. There was a puffy septum of granulating tissue between the ends of the fragments. Above there was evidence of extravasated blood, and two and one half inches above the line of fracture there was a small circumscribed medullary abscess. The medullary cavity was inflamed and streaked with red lines.

Through the kindness of Professor Brinton and Dr. Longstreth, Dr. Wilson was enabled to show several pictures illustrative of osteo-myelitis. This is the only case of death from simple fracture recorded at the Pennsylvania Hospital. This disease must be a very rare sequel of simple fracture. It is not necessarily a fatal disease, as the inflammation may become circumscribed, a depot of pus formed, and the destructive processes end there, or a portion or the whole of a bone may die or be removed. It is easy to see how a virulent inflammation going on to suppuration with no vent to the pus, as in this specimen, could readily give rise to septic poisoning. I am indebted to the courtesy of Dr. Longstreth both for the specimen and assistance in its preparation.

Dr. Tyson said that he had seen many cases of osteo-myelitis from gunshot injuries during the late war, but he could not recall a case where the medullary canal was encroached upon by a condensing osteitis, as in this specimen.

Dr. Nancrede related a case of fatal septic trouble following a simple fracture of the thigh, where the starting point seemed to him to have been a superficial ulceration of the skin, produced by the adhesive plaster. Possibly section of the bone might have revealed an osteo-myelitis, but as the fracture was firmly united, he thought that the skin abrasion was the starting point, and related two cases of pyæmia produced by equally trivial causes.

Dr. Longstreth related a case seen by him when a resident physician at the Pennsylvania Hospital. The patient had a fracture of the thigh of three weeks' standing, and was apparently doing well, when chills, sweats, lung consolidation, etc., etc., ushered in a fatal attack of pyæmia. A post mortem revealed osteo-myelitis and general pyæmic manifestations. A possible explanation of Dr. Wilson's case was that the man had been on board ship for three weeks after his injury, where the treatment must have been of the crudest description.

Dr. Eskridge called attention to the endocardial trouble found in septic disease, which he had been taught as a student to consider was of an ulcerative form, and of fatal prognostic import. He had, however, seen two cases which presented all the symptoms of ulcerated endocarditis, but which had recovered, while in two others with a similar clinical history post-mortem examination revealed only a simple non-ulcerative endocarditis.

Dr. Shakspeare asked whether this condensing osteitis might not have been due to a previous syphilitic trouble.

Recent Literature.

A Manual of Psychological Medicine and Allied Nervous Diseases. By Edward C. Mann, M. D. Philadelphia: P. Blakiston, Son & Co. 1883.

This book on insanity comprises 700 full-grown pages, to say nothing of some illustrations. Why it should be called a "manual," unless because it was written by Mann, we are at a loss to see, as Worcester defines a "manual" as "a small book, such as can be carried in the hand," and this book is large enough to be carried around in a shawl strap. The original contents, however, if boiled down, would easily go into the vest pocket.

Dr. Mann has adopted the old-fashioned plan of bringing together a large amount of material from a great variety of very good authors, and has strung this together on a slender and often invisible thread, and with so little *zusammenhang* that sometimes there is little relevancy.

His History of Insanity covers one page. Next he begins on Classification, recommending the simple and childish system of Krafft Ebing. This covers two pages. On the middle of the next page he branches into the making of autopsies. On the next page he gives definitions of insanity until he suddenly remembers that he was on the subject of classification, and returns to this again toward the bottom of the page.

After a short chapter on the Ætiology of Insanity, he has a chapter of two pages on the Prevention of Insanity. Why he breaks in on the usual custom followed, and puts in a few words just here on this subject instead of at the end of the book, he does not say.

Chapter IV. has nineteen pages on the Diagnosis and Prognosis of Insanity. Chapter V., sadly out of place, has eight pages on Civil Incapacity. Chapter VI. has nine pages on General Paralysis of the Insane, of which Dr. Mann has the very correct idea that it should be called general paralysis because it is no paralysis in particular. Chapter VII. treats of Idiocy, Dementia, Folie Raisonnante (Syn., Moral or Affective Insanity)."

After a chapter on Mental Responsibility, etc., in Criminal Cases comes a chapter on The Histology and Functions of the Cerebrum.

These specimens of the arrangement of the book will show with what incongruity and lack of system the book is written, and as these faults are combined with those of general incompleteness and a marked lack of thoroughness of treatment of most of the subjects discussed we should say that time would be utterly wasted in reading the book.

We regret the necessity, but it becomes our solemn duty, in the interests of good psychological writing, to openly declare that this book, in our opinion, is a complete *failure.*

— On account of the departure of the Senior Editor, Dr. Pilcher, for Europe, in January, and the expected departure of his colleague, Dr. Fowler, for a similar trip abroad later in the season, the publication of the *Annals of Anatomy and Surgery* is necessarily suspended during their absence.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 7, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE SIMULATION OF STONE.

FEIGNED diseases form an exceedingly interesting class of cases, though the majority of malingerers fall under the notice of the military and naval rather than of the civil surgeon. In times of general conscription such attempts at fraud are most frequent, and show the greatest ingenuity on the part of the malingerers, calling for equal acuteness for their detection. In France the time of the first Empire was most prolific in such attempts to escape military duty, and many will recall the published lists of the exempt and the disease on which their exemption was founded during the conscription at the close of our late civil war. But even the quietest and least suspicious of civil practitioners is liable to be deceived, as some of the most carefully studied attempts at deceit have been devised and executed without the exciting stimulus of the desire to avoid military duty. One of the most baffling cases was given in this journal some three years ago of the "dummy chucker," or executor of epileptic fits, for the opportunity offered to his accomplices, during the excitement attendant on the fit, of robbing the bystanders. Few cases are so skillfully executed as in the case of this criminal, who boldly "chucked his dummy" in the court room and in hospital wards.

The feigned diseases embrace a wide list of subjects, and under the same general heading which includes the fraud who simulates a disease which he has not must be classed the individual who, wounded or sick, exaggerates the gravity or conceals the cause of the complaint.

An important contribution to the literature of feigned diseases has recently been made by Dr. Brongniart, of Contrexéville. He narrates three cases, all females, which have come under his own observation, in which the pretense was made that stones had been passed from the bladder, and these pretended calculi were preserved and exhibited. Twenty-two similar cases are referred to as found in the literature of the subject, of which one was a man, four were boys, and the rest females. The only adult male case is one narrated by Civiale of an officer who claimed to have been cut for stone just after the retreat from Moscow. The stone that he exhibited was remarkable for its size and polish; a section proved it to be but a common pebble. Reverence for the great lithotomist forbids us to intimate the possibility that both narrator and officer were deceived by the "Jewish surgeon," who desired to retain the fruits of his own prowess and presented to his patient the most convenient substitute. Of the boys, the most interesting case is that of a little fellow of ten years, sent in 1791 to Deschamps for lithotomy. His mother showed pebbles which she had seen issue from his meatus. The boy actually had a stone, was cut, and a true calculus removed at the Charité, and after his recovery confessed that fear of the operation with which he was threatened had induced him to persuade his mother that he was passing the stones himself without the assistance of a surgeon.

The three cases of Brongniart have little if any relation with those numerous cases in which erotic individuals of both sexes introduce various articles into the urethra; they are rather manifestations of a hysterical neurosis. The patients did not always introduce the false calculi into their bladders, but contented themselves with the declaration that they were found in the bed or the receptacle of urine. Had they taken the precaution to procure genuine urinary concretions for exhibition it might have been impossible for the physician called in after their pretended nephritic colic to have discovered or even suspected the fraud.

Suppose that the doctor has, from some point in the appearance of the gravel, a doubt of its authenticity, which is converted into certainty by chemical analysis, shall he consider it as an ordinary deception without motive? Shall he reject as false all the patient's sufferings? Our author does not believe it. It is one's duty, on the contrary, to inquire carefully into the history and heredity of the patient, and if hysteria is manifest in herself or her parents he will perhaps find that the simulation is the consequence of a painful form of hysteria, of a nephralgia, or a cystalgia, of which the real pain must not be overlooked by the discovery of the added deceit. Various authors are cited to show that hysteria may provoke painful phenomena and functional trouble on the part of the urinary organs. One can then easily imagine that a nervous woman, perfectly honorable, without a premeditation of deceit, may be attacked with a hysterical nephralgia so resembling nephritic colic as to deceive even the attending physician. "All the world," commencing with the patient, believe in the existence of the gravel; but after many returns of the attack and no appearance of anything to confirm that opinion one begins to doubt the truth of the diagnosis. The terms "nervous attack," "hysterical crisis," come to the ears of the patient, and to avoid the unpleasant name hysteria she takes pains to demonstrate at her next attack the reality of her pain. A course of deception once entered upon she will not willingly inculpate herself, and the deception may be continued for months and even years.

One of these cases must serve as a sample of the class.

Mlle. B., eighteen years of age, slightly chloro-anæmic, was subject to various nervous accidents. These nervous attacks were attended with very acute

lumbar and abdominal pain, difficulty of micturition, and convulsive movements. Having had occasion to assist in the care of an aunt suffering from nephritic colic, Mlle. B., after one of her painful crises, showed gravel which she said she had found in her urine, and more was found in her bed. There was no longer doubt in the mind of her physician as to the character of her disease; she had nephritic colic, and was sent for treatment to Contrexéville. The young girl belonged to an excellent family, and there was no reason to suspect the truth of the story, but the father had brought with him and showed to Dr. Brongniart the gravel, which was seen to be made up of particles of quartz and fragments of brick. At a private interview, the father refused entirely to believe in the Dr.'s explanation, and the suspected gravel was forwarded to Dr. Méhu at Paris for examination. An answer was returned which convinced the father, who became vehement in denunciation of the falseness of his daughter, whose defense the doctor was obliged in his turn to undertake. He told the angry parent that the pains suffered by his daughter were real, that the nervous crises were not simulated, but that they were of a hysterical nature, and that hysterical people were often uncontrollably impelled to reprehensible acts, as, for instance, simulation or theft, without it being possible to consider them actually responsible for these unhealthy impulses. This was a ray of light for the unhappy father, who then revealed certain facts in the history of the mother of the young deceiver, who had been the victim of kleptomania, taking the most worthless objects, necessitating her temporary detention in an asylum.

This nervous heredity explained and excused to a certain extent the simulation of which the young lady was rendered guilty under the combined influence of an imitative impulse and the neuralgic pains of hysterical character. The urine, though often examined, was always found absolutely normal in this case. A suitable regimen was prescribed, and nothing more was heard of the case.

Our limited space permits us only to add the conclusions which Dr. Brongniart draws from his consideration of the subject: —

The simulation of urinary gravel observed sometimes in young boys is much more frequent among females.

The motive for that deception in boys may be that of all other deceptions, idleness, the desire of exciting interest and pity; perhaps erotic motives.

In women and girls the same motives may exist as in boys; much more likely in them are erotic motives as a determining cause. Nevertheless, outside of all depravity, the simulation of urinary calculi may be determined by hysteria under the form of nephralgia: with the purpose of evading the ill-sounding epithet of hysterical, these invalids prefer to give to their sufferings the name of nephritic colic, which induces them to show the fictitious stones.

One ought always to analyze with care the urine and gravel from young boys and nervous women who declare themselves afflicted with stone.

BOSTON'S IMPROVED SEWERAGE SYSTEM.

On the first day of January the new system of intercepting and delivering sewers for that part of Boston situated between the Charles and Neponset Rivers, which has been in construction for a number of years, was inaugurated. Members of the Massachusetts Medical Society will recall that they were invited during the last annual meeting of the Society to inspect the main sewer, and those who did so are somewhat familiar with the system of which it forms a part. As the growth of the city demanded, sewers were built years ago, each emptying at a locality most convenient and least annoying. According to the new plan a series of intercepting sewers has been constructed belting the city and communicating with the older sewers near their mouths by means of small branch or connecting sewers, provided with gates to regulate the flow. The old outlets are to be for the most part kept open, to be used for storm overflows, and those below tide level will be provided with a double set of gates to prevent the tide from flowing in.

The great bulk of the sewage is, however, by the new system to be conveyed to a considerable distance from the shore, and deposited where it is believed, and thus far proved, that it will not be obnoxious or injurious. The various intercepting branches converge into one main sewer, which runs in nearly a straight line to old Harbor Point, Dorchester, where there is a pumping station. At this point extensive works have been erected, the first of which is a filth hoist, through which the sewage passes before it reaches the pumping station. The filth hoist consists of two chambers, in each of which are hung, so as to be raised and lowered by winches, open cages through which the sewage flows and which retain any large floating objects that would injure the pumps. They are arranged in pairs, one behind the other, so that one may be in place while the other is drawn up for cleaning. Four engines, each of a capacity to raise 25,000,000 gallons in twenty-four hours to a maximum height of forty-three feet, are now in position, and it is designed eventually to double this pumping capacity, allowance having been made for two boiler houses.

The outfall sewer extends from near the engine house to the reservoir on Moon Island, a distance of a little more than two and a half miles. The first portion of the outfall sewer, a section of 1200 feet, is the deposit sewer, which is carried into Dorchester Bay on an embankment; the second portion, having a horizontal length of 6970 feet, is the tunnel under the bay in the form of an inverted siphon, at whose entrance is a vertical descent of 150 feet, the level being regained at the farther end by a rise of one foot in six; the third portion extends from Squantum Neck on the farther side of Dorchester Bay to Moon Island, where it connects with a reservoir having four compartments with a total capacity of 25,000,000 gallons, from which the sewage is discharged at ebb tide into deep water by an outlet sewer.

The total estimated cost of these sewers for the south side of Charles River, including an allowance of

$300,000 for rebuilding and connecting old sewers, was placed in 1876 at $3,750,000. The actual cost has been thus far about $4,500,000, and $750,000 more will be needed, but much of the work proved far more difficult than was expected, and several contractors met with serious losses. The important thing is that the work seems to have been well done, and the system to practically answer the expectations that were formed of it. For the district on the north side of Charles River a main sewer and branches of fifteen miles length with other works, at a cost of more than $3,000,000, will be required, but are not yet contracted for.

In addition to relieving the waters of Charles River and its flats, which had become extremely offensive, the present sewers, providing for a constant and uninterrupted flow of sewage from its entrance to the outfall sewer, deliver the city from the cess-pool tendency of the old sewers; whether the level of the ground-water will be lowered, as was at one time anticipated, it is as yet too early to determine.

It will be easily seen that with the surface drainage of the city and the great consumption of water, — between ninety and one hundred gallons per head daily, — the sewage, when reaching Squantum or the reservoir on Moon Island, will be extremely dilute, yielding but a small percentage of solid constituents and those of a soluble character. It is not reasonable to anticipate any annoyance from its discharge into deep water on an ebb tide, either to those navigating this outer portion of the harbor or to those occupying neighboring shores; the full sewage product of the district drained is not as yet discharged through the intercepting sewer, but of the large amount which is discharged all trace is dissipated in the ocean even more readily than was anticipated. Whether any other disposition could be advantageously made of this sewage when once delivered at Squantum or at Moon Island is a subject whose discussion we reserve for another occasion. Enough is already known, however, of the working of the present system to permit us to say that those who designed and executed it deserve well of the city, as will doubtless be evidenced in due time by a diminished death-rate, and more immediately by a relief of offended senses.

CREMATION IN CHINA.

In the last issue of the Chinese Imperial Maritime Customs Medical Reports Dr. A. Henry contributes some remarks upon cremation in that country. Marco Polo repeatedly asserts that the Chinese wherever he traveled were in the habit of burning their dead; on the other hand Chinese historical works make no mention of the practice, and burial is the almost universal custom at present. The books in which the subject of cremation in China is treated only speak of it as being practiced upon the bodies of Buddhist priests and lepers. In only one, however, of the many Buddhist temples at the town where Dr. Henry is stationed are the bodies of the inmates burned after death. The method of incineration is commendable as efficient, æsthetic, and inexpensive; but it is too slow except for Buddhist priests in China. In the grounds of the temple is a small dome-like edifice, the interior of which communicates with the open air by a small door only — a charcoal kiln, in fact. The dead priest is placed in a sitting posture inside the dome, and charcoal and firewood are piled around him; fire is applied, and the door is shut until combustion is complete.

Children are sometimes cremated, but for superstitious reasons only. When several young children of a family have died in succession the body of one of them is burned under the belief that this ceremony will insure the survival of the next child born to the family. In these cases the body is simply brought to an open field in a box and placed upon firewood which is ignited.

China and India are preëminently countries in which a rational system of cremation might be encouraged with much advantage.

MEDICAL NOTES.

— Patrick B. Tully, a new representative in Congress from California, has introduced in the House a bill refusing the privileges of the mails to the advertisements "of any medical preparation, compound, or prescription, or any punch, bitters, cordial, or similar compound or preparation to be used as medicine or mixed with food, liquor, wine, or other substance used as a beverage or as food or medicine," unless the manufacturers thereof can procure from the Federal Patent Office a certificate that it is not noxious or dangerous to health. The progress of this bill will be watched with interest, but it will doubtless be beset with many difficulties, so that prognosis for its survival should be very guarded.

— M. Paul Bert is not, as the sound of his name might suggest, a hyperborean, but a French *savant* who has made an "eloquent" plea against the American hog before the Legislative Chamber. His views on the liability of trichiniasis resulting from American pork are contrary to those of most other leading scientists of Europe. The persistency of his attack and the resulting legislation have opened the eyes of some American traders to irregularities in the composition of French wines and liqueurs of which they were before oblivious. The principal point of medical interest in the argument of M. Paul Bert, however, is his statement that trichiniasis is more frequent in France than generally believed, owing to its being often mistaken for typhoid fever. Though there is an implied compliment to the therapeutic ability of the Frenchmen in that the recent mortality of their so-called typhoid fever exhibits no increase even though it is the result of an average between the mortality of trichiniasis and true typhoid, still as a reflection on the diagnostic and pathological acumen of his countrymen the remarks of M. Paul Bert must have had a frigorific effect.

— It is said that the tooth manufacture of the United States amounts to 10,000,000 teeth per annum. There are twelve manufactories, but one of them, founded in 1864, makes half the number. The

value of these teeth is a million dollars. The materials of which they are composed are feldspar, kaolin, and rock crystal.

— Dr. Lemoyez, writing to the *Bulletin Générale de Thérapeutique*, recommends parenchymatous injections of pure sulphuric ether for sebaceous cysts of the face and scalp. A case is reported of a man who was relieved of a wen of five years' growth by ten hypodermic injections of ether practiced at intervals of a day or two. The result was the conversion of the tumor into a cyst with fluid contents, the evacuation of the same, and speedy destruction of the cyst wall by inflammatory action. The injections are made into the interior of the cyst, five or ten drops at each sitting, the needle of the hypodermic syringe being moved about so as to break up the contents as much as possible. They are discontinued when inflammation or suppuration begins. In the case quoted the treatment resulted in a perfect cure in a month without keeping the patient in bed or restricting his movements as would have been required by the ordinary operation.

— The New York *Times* of January 12th contains an editorial on the Longevity of Doctors, which the editor evidently thought would be amusing to his readers. So it is. The article is based on the list of English practitioners who have died at an advanced age during the last four years. The writer attempts to account for their long life by enumerating in a serio-comic strain the healthful features of a doctor's life, chief among which he places the fact that doctors as a rule swallow little medicine. He then enumerates the pleasures which his profession yields him, and gives vent to the following sentence: "The physician meets with quantities of interesting diseases, and is always hoping to be the first to describe some new disease to which his name will be forever attached, like the popular diseases discovered by Messrs. BRIGHT and COX respectively!" Evidently the funny man's Latin enables him to translate *morbus Coxæ* into Cox's disease.

NEW YORK.

— Truly this is the age of progress (?). At the last meeting of the County Medical Society (New Code) a resolution was adopted urging the passage of a pending bill before the Legislature establishing a State Medical Board of Examiners *composed of regulars, homœopaths, and eclectics*, whose prerogative it shall be to determine upon the qualifications of candidates for the degree of Doctor of Medicine, now vested in the various medical colleges. The bill provides that the examiners shall be appointed by the Governor.

— The fourth course of the Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons was delivered in Association Hall by Prof. Burt G. Wilder, M. D., of Cornell University, on the evenings of February 2d, 4th, and 6th, his subject being Methods of Studying the Brain. The first lecture was devoted to a consideration of the limits of the subject of macroscopic encephalic morphology and the methods of regarding the brain based upon its condition in embryos and in amphibia; the second to the methods of preserving and examining the brain; and the third to the methods of figuring and describing the brain.

— A slight fire occurred in Charity Hospital January 27th, which might have been serious had it not been for the presence of mind and energetic action of Dr. Seaman, chief of staff. It occurred at 5.15 in the morning on the third floor of the section of the building occupied by the house physicians and surgeons, and one of their number, Dr. Weiss, was nearly asphyxiated with smoke. It was thought that the fire was caused by the steam-heating pipes.

— Mayor Low, of Brooklyn, has reappointed Dr. Joseph H. Raymond Commissioner of Health of that city.

— Dr. Elisha Harris, secretary of the State Board of Health, died of peritonitis, after a brief illness, at Albany, on the 31st of January. He was born at Westminster, Vt., March 5, 1824, and received the degree of M. D. from the College of Physicians and Surgeons, New York, in 1849. In 1855 he was made superintendent and physician-in-chief of the quarantine hospitals on Staten Island, and during the greater part of the late war he was a member of the National Sanitary Commission. For a number of years afterward he was connected with the New York Board of Health, and on the organization of the State Board of Health, in 1880, he was appointed its secretary.

Correspondence.

LETTER FROM LONDON.

LONDON, *January* 24, 1884.

MR. EDITOR, — At his last ovariotomy Mr. Knowsley Thornton remarked that if the case then on the table recovered, — and he saw no reason why she should not, — it would complete a line of seventy cases which he had done at the Samaritan Hospital within the two years ending February 23, 1884, *without a death*.

As I happen to know personally, these cases have not been "picked," but represent all grades and conditions of ovarian tumors.

If we go back some forty-five or fifty years to the time when Bright was engaged in writing his famous papers on abdominal tumors, and compare that period with the present, we are forced to exclaim that the stride made by abdominal surgery is little less than miraculous. Then it was the practice to puncture the abdomen and draw off the contents of the tumor as often as it refilled and became troublesome, or until the unfortunate patient died of exhaustion or peritonitis or from septic poisoning produced by suppuration of the growth. Then opening the abdomen was an experiment little resorted to, and when attempted generally resulted in such disaster that even progressive men like Bright were inclined to look upon it with suspicion and disfavor. On this point he says: "I believe as far as *cure* is concerned the malignant ovarian dropsy admits of none unless we may consider the excision of the tumor in that light, and *this must ever*

be so doubtful an operation, surrounded by so much darkness and attended with so much danger, that I can only look upon its happy event as the fortunate result of a bold and hazardous enterprise, which should not tempt us to adopt it as a rule of practice." [1]

What would Bright have said could he have penetrated the future and foreseen Keith's seventy-six consecutive "excisions of the tumor," without a death, and now Mr. Thornton's brilliant results?

Until Professor Bigelow demonstrated to the contrary, surgeons were always talking of the intolerance of the bladder and urethra, making this a *bête noir*. The peritonæum has also been considered in a similar light, and only within the past few years have surgeons begun to learn that it is not so very intolerant after all, and admits of some pretty rough handling without any particular danger to the patient.

Armed with this knowledge and Listerism the specialist now seems ready to attack any of the abdominal morbid growths, and with a tolerable certainty of success. I say *specialist*, for I do not believe that the general surgeon, however skillful and learned he may be, can compete with one who devotes a large part of his time to abdominal surgery alone, and the many opportunities which I have had of witnessing operations by both verify the statement.

On the 18th inst. Mr. Thornton removed by laparotomy a large fibro-cyst of the uterus, amputating the latter near the middle of the cervix. The spermatic arteries having been tied, Koeberlé's *serre-noeud* was used to constrict the cervix. The "stump" was treated by the extra-peritoneal method. It is now the fifth day since the operation, and the patient is doing well.

On the 8th Mr. Meredith operated on a hydatid cyst of the liver. This case is of especial interest, as the patient came under Mr. Meredith's care about a year ago and underwent a similar operation; the one case I know of where the same abdomen has been twice opened for the removal of hydatids. The patient is now convalescent.

Both Thornton and Meredith continue to use the spray, and operate in a thoroughly antiseptic manner; and I fancy that their excellent results are partially due to this fact.

At the last meeting of the Obstetrical Society of London a very interesting paper On Observations of Puerperal Temperature, by Dr. E. S. Tait, was read. The article dealt almost exclusively with the relation of nervous impressions or disturbances to post-partum rise of temperature.

The observations were made in one of the London lying-in hospitals, and are a valuable contribution to the literature of the subject. The paper provoked an animated discussion, in which the President, Drs. Mathews Duncan, Playfair, Graily Hewitt, Williams, Champneys, and others joined.

Dr. John Williams's paper on Corroding Ulcer of the Os Uteri, was deferred until the next meeting. The specimen, however, was exhibited, and by courtesy of Dr. Williams I saw the drawings which will be used for illustrations. It is to be hoped that this paper, emanating from so high an authority, will throw some light on the ætiology of this very obscure disease, which Emmet says "is almost as rarely met with as is true sarcoma."

The new antipyretic *kairin*, discovered last year by Fischer, of Munich, does not appear to be gaining favor, although I heard Heywood Smith say last week that he had used it with success in a case of high temperature after the removal of an ovarian cyst. Quinia had failed to bring down the temperature after repeated and large doses; but a few doses of kairin had the desired effect.

Since my last letter I have seen Sir Joseph Lister operate by his wiring method both on a fractured patella and on the olecranon. The cases did well. This method of wiring the fragments of bone together is, I believe, steadily gaining ground, although it is still stoutly opposed by the older surgeons.

Very truly yours, W. P. MANTON, M. D.

[1] The italics are mine.

Miscellany.

FATAL RESULT FROM INJECTION OF THE TUNICA VAGINALIS WITH IODINE.

DR. JOHN A. WYETH reports in the *Annals of Anatomy* (January, 1884) a case where death followed the medical treatment of hydrocele by injection of iodine. The patient was forty-three years of age, of good family history. Had had syphilis and gonorrhœa, the latter several times, but no symptoms of any unusual lesion for at least three years. The hydrocele on the left side was of three months' standing at the time of operation. The urine contained a trace of albumen and pus, supposed to be the *liquor puris*. In the operation, which was done June 27th, the method advised by Van Buren and Keyes was followed. The fluid, measuring about eight ounces, was drawn off with a medium-sized aspirator needle, and one half the quantity of tincture of iodine was thrown in and immediately drawn back into the aspirator. A small quantity, estimated at about one half an ounce, would not return through the needle, and was allowed to remain in and to trickle out through the trocar wound.

Pallor and other evidences of slight shock followed the operation, which was done at ten A. M. At four P. M. patient had a chill lasting fifteen minutes, followed by delirium and a rapid pulse scarcely perceptible at the wrist. Half an ounce of whiskey was given *per os*. By this time a dark-blue spot, insensible to the touch and as large as a silver dollar, had made its appearance on the scrotum, extending to the median raphé. A free incision was now made into the tunica vaginalis through this spot, the cavity was washed out, and the scrotum covered with a poultice. The iodine which was left in was washed out, together with a few small brown clots, which seemed to be coagulated hydrocele fluid, stained with iodine. Urine passed six hours after operation was colored with iodine, and the breath had a peculiar odor. Temperature on this day was, at 3.40 P. M., 101° F.; 4.20 P. M., 102° F.; eight P. M., 99.8° F.; ten P. M., 99.7° F. Quantity of urine in first twenty-four hours, ℥xv.

June 28th. Temperature from one to eleven A. M., 99° F. At two A. M. passed ℥v. dark urine. Slight vomiting, and again at nine A. M., after taking milk. Cellulitis of scrotum, penis, and contiguous skin of abdomen. One P. M., temperature 101° F.; four P. M., temperature 102° F.; urine, ℥ixss.

The next few days sloughing of the scrotum occurred, poultices were applied, and the patient was in general comfortable with temperature never above 101° F. The urine averaged about twelve ounces.

On July 4th patient was seized with a severe diar-

rhœa, followed by eleven evacuations, which greatly prostrated him before they could be checked with quinine, bismuth, and opium; urine, ℥xv.

The next day, at six A. M., while attempting to sit up in bed and lift himself by his hands, he cried out as if in great pain, and fell back instantly dead. An autopsy was refused.

The immediate cause of death was believed by the author to be severe diarrhœa, which, supervening on the bad condition of the man, caused heart failure. The absorption of the iodine was the entering wedge, which was followed by the other accidents. Uræmia is excluded, from the amount of the urine and the sufficiency of urea. The author's conclusion is that the open operation, that is, free incision, with stitching of the parietal layer of the tunic to the integument, and the introduction of a drainage tube into the cavity, is the safest and surest operation.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 26, 1884.

[1] Twenty cases recorded at New Bedford drowned at Gay Head.

Deaths reported 2822 (no report from Buffalo): under five years of age, 978: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 424, lung diseases 460, consumption 396, diphtheria and croup 146, scarlet fever 80, typhoid fever 50, diarrhœal diseases 37, measles 33, malarial fevers 28, whooping-cough 20, small-pox 17, cerebro-spinal meningitis 17, puerperal fever 14, erysipelas 11, typhus fever one. From *diarrhœal diseases*, New York 11, New Orleans eight, Brooklyn five, Boston three, St. Louis, Baltimore, and Cincinnati two each, Chicago, Nashville, Cambridge, and Holyoke one each. From *measles*, Baltimore 11, New York seven, Brooklyn and District of Columbia five each, Philadelphia two, Chicago, Nashville, and Worcester one each. From *malarial fever*, New York and New Orleans six each, Chicago five, Brooklyn four, St. Louis three, Baltimore, two, District of Columbia and New Haven one each. From *whooping-cough*, New York four, Baltimore and District of Columbia three each, Brooklyn two, Chicago, Boston, St. Louis, Cincinnati, New Orleans, Nashville, Worcester, and Chelsea one each. From *small-pox*, New Orleans 16, Philadelphia one. From *cerebro-spinal meningitis*, New York six, Philadelphia and Worcester three each, Chicago, New Orleans, New Haven, Cambridge, and Somerville one each. From *puerperal fever*, Boston five, Chicago three, Brooklyn two, Philadelphia, St. Louis, Cincinnati, and Lowell one each. From *erysipelas*, New York, Chicago, and Lowell two each, Philadelphia, Brooklyn, Boston, St. Louis, and Baltimore one each. From *typhus fever*, New York one.

Eight cases of small-pox were reported in St. Louis, Cincinnati one; scarlet fever 59, diphtheria 29, and typhoid fever seven in Boston.

In 105 cities and towns of Massachusetts, with an estimated population of 1,319,006 (estimated population of the State 1,922,530), the total death-rate for the week was 17.78 against 20.00 and 18.00 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 12th, the death-rate was 21. Deaths reported 3523: acute dis-

eases of the respiratory organs (London) 379, scarlet fever 117 measles 116, whooping-cough 99, fevers 51, diphtheria 32, diarrhœa 29, small-pox (Birmingham seven, London and Sunderland two each, Liverpool one) 12. The death-rates ranged from 13.7 in Portsmouth to 28.9 in Norwich; Bristol 17.2; London 91.4; Birmingham 20.2; Sunderland 20.8; Nottingham 21.1; Bradford 21 4; Newcastle-on-Tyne 22.8; Liverpool 23.7; Sheffield 25.5; Manchester 28.4. In Edinburgh 18.8; Glasgow 25.8; Dublin 27.1.

For the week ending January 12th, in the Swiss towns, there were 36 deaths from consumption, lung diseases 22, diphtheria and croup 11, diarrhœal diseases 10, whooping cough six, measles three, scarlet fever three, typhoid fever two, small-pox one, erysipelas one. The death-rates were, at Geneva 19.4; Zurich 5.9; Basle 20.9; Berne 23.3.

The meteorological record for the week ending January 26th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date. Jan., 1884.	Barometer. Daily Mean.	Thermometer. Daily Mean.	Thermometer. Maximum.	Thermometer. Minimum.	Relative Humidity. 7.23 A. M.	Relative Humidity. 3.23 P. M.	Relative Humidity. 11.23 P. OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM JANUARY 25, 1884, TO FEBRUARY 1, 1884.

ALEXANDER, CHARLES T., major and surgeon. So much of paragraph 7, S. O. 211, September 14, 1883, as directs him to report in person to the commanding general, Department of the Missouri, for duty, is revoked, and he will, upon the expiration of his present leave of absence, proceed to St. Louis, Mo., and assume duty as attending surgeon and examiner of recruits in that city. Paragraph 1, S. O. 21, A. G. O., January 25, 1884.

ELBREY, FREDERICK W., captain and assistant surgeon. Present leave of absence extended six months. Paragraph 9, S. O. 24, A. G. O., January 25, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING FEBRUARY 2, 1884.

BATTLE, S. W., passed assistant surgeon. Detached from the U. S. S. Gedney and placed on sick leave.

CORRECTION.

MR. EDITOR, — I ought to have stated in my article on Nephrectomy, which you published January 24th, that the form of table was taken from an article by Mr. Barker, in Vols. LXIII. and LXIV. of the Medico-Chirurgical Transactions, and that cases numbered 1, 3, 4, 6, 7, and 14 were found in his table.

Very sincerely yours, JOHN HOMANS.

OBITUARY.

JOHN L. CLARK, M. D., fifty-five years of age, a ward master in the Boston City Hospital, died recently in that institution of pneumonia. The deceased was a well-educated man, and was graduated at the Harvard Medical School in the class of 1861, with Drs. Blake and Edes, now visiting physicians to the City Hospital. He served in the Union Army as an assistant surgeon until the war was over. He then practiced medicine for a time in Providence, R. I., but subsequently suffered pecuniary misfortune. Previous to his entering the service at the City Hospital he was steward at the Massachusetts General Hospital.

APPOINTMENTS. — Dr. Charles M. Green has been appointed assistant in obstetrics in the Harvard Medical School.

Mr. Charles F. Donnelly has been again appointed by the Governor on the Massachusetts Board of Health, Lunacy, and Charity to fill the vacancy caused by the resignation of Dr. Robert T. Davis, M. C.

DEATH. DR. JOSHUA JEWETT JOHNSON. — Died, in Northborough, Mass., January 29, 1884, Joshua Jewett Johnson, M. D., M. M. S. S., aged seventy-four years nine months.

BOOKS AND PAMPHLETS RECEIVED. — Hints on the Drainage and Sewerage of Dwellings. By William Paul Gerhard, Civil Engineer. New York: William T. Comstock, 6 Astor Place. 1884.

Report of Proceedings of the Illinois State Board of Health. Quarterly Meeting, Springfield, January 17, 18, 1884.

A Manual of Practical Hygiene. By Edmund A. Parks, M. D., F. R. S., late Professor of Military Hygiene in the Army Medical School, etc. Edited by F. S. B. François De Chaumont, M. D., F. R. S., Fellow of the Royal College of Surgeons of Edinburgh, Professor of Military Hygiene in the Army Medical School. Sixth Edition, with an Appendix giving the American Practice in Matters relating to Hygiene, prepared by and under the Supervision of Frederick N. Owen, Civil and Sanitary Engineer. Vol. II. New York: William Wood & Co. 1883. (November Number of Wood's Library of Standard Medical Authors.)

The Relation Dairy Products bear to Disease. By Hugh Hamilton, M. D., Harrisburg, Pa. (Reprint.) 1884.

Transactions of the American Gynecological Society. Vol. VIII. For the Year 1883. New York: D. Appleton & Co. 1884.

So-Called "Concussion of the Spine" in Railway Injuries. By John G. Johnson, M. D. New York.

Eighteenth Report of the Board of Trustees of the Connecticut Hospital for the Insane. 1884.

Morbid Somnolence. By Rudolph Matas, M. D. Read before the New Orleans Medical and Surgical Association.

Trismus Nascentium, or the Lockjaw of Infants: Its History, Cause, Prevention, and Cure, etc. By J. F. Hartigan, M. D., of Washington, D. C. (Reprint from American Journal of the Medical Sciences.)

Annual Address delivered before the American Academy of Medicine at New York, October 10, 1883. By Henry O. Marcy, A. M., M. D., President of the Academy.

Original Articles.

TWO CASES OF ABDOMINAL SECTION TO DISCOVER THE CAUSE OF INTESTINAL OBSTRUCTION.[1]

COLOTOMY BY THE MEDIAN INCISION IN ONE CASE, AND OPENING OF THE CÆCUM BY A LATERAL INCISION OF THE ABDOMINAL WALLS IN THE OTHER.

BY JOHN HOMANS, M. D.,
Surgeon to the Massachusetts General Hospital.

MRS. R., aged forty-three, who had recovered from ovariotomy in May, 1881, and had enjoyed fair health since her recovery, began to suffer from constipation in the autumn of 1881.

Her medical attendant, Dr. J. H. Richardson, of Medfield, Mass., wrote to me (I give his exact words) on December 15th, as follows: "I was called to see Mrs. R., whom you no doubt remember, last Sunday, December 11th, and found that she had had an increasing constipation for the last two months, the last dejection was December 6th, and there has been none since to amount to anything. She has been quite comfortable most of the time with the exception of colic pains occasionally. Pulse has been 80 to 84, her temperature 100° F. Treatment at first small repeated doses of castor oil, and later saline laxatives and a diet of gruel. No opiate has been required but once."

On the 16th Dr. Richardson writes: "I find Mrs. R. very comfortable. There is now no distention of the abdomen, flatus passes readily, and she does not look sick. I examined the rectum and found nothing. She has been able all the while to take injections of three pints or more and retain them for one or two hours, then they come away freely without color or odor. How long can this last without change of some kind?"

Again on the 17th Dr. Richardson writes: "Our patient, Mrs. R., continues very much the same. During the last twenty-four hours flatus passed much less readily, and there was more fullness of the bowels, but very little pain. She sleeps well, and is quite comfortable. Since the 8th inst. I do not think the amount of a teaspoonful of solid fæcal matter has passed the bowels."

On the 19th he writes: "For thirty-six hours no flatus has passed, and I found her this morning a little uncomfortable from the distention of the bowels. Last evening she took one eighth grain of morphia. I call the bowels a good deal distended to-day. Pulse 80, and normal. It seems to me there can hardly be any doubt about the case looking rather serious. She has shown no fever or alarm, and she thinks you are going to stand by her through this siege."

On the next day he writes: "I saw our patient this morning, and found that her stomach had not retained much given yesterday, and she looked a little worn. Pulse and temperature the same, the bowels apparently no more distended but more painful, and she had rejected the morphia powder last night. I gave this morning morphia subcutaneously and nutrient injections. I don't know as I have any reason to expect relief without surgical interference, and how long to wait is the question. It seems to me that to-morrow or next day at farthest, — perhaps to-morrow, — it would be desirable for you to see her."

I have given Dr. Richardson's letters as he wrote them because they convey a very clear idea of the state of the case during the two weeks preceding the operation. On December 21st I saw the patient at her home, and explained to her that an exploratory incision might reveal some band or adhesion resulting from the cicatrization following the removal of the ovarian tumor, and that this I might be able to divide or separate and completely relieve her, or that I might find the obstruction not removable and have to make an artificial anus. She was a woman of remarkable coolness, quietness, decision, and courage, and she said that she should like to prolong her life for the sake of her boy, and that she wished me to operate and do the best I could under the conditions I should find. At this time the abdomen was somewhat distended, but not hard, and the peristaltic movements of the bowels were active and very visible to the naked eye, looking as if the vermicular motion was a sort of vibration which moved to a certain point and then returned by a vibration in the opposite direction. This was continuous. The pain was severe, but not unbearable, and the countenance looked pale and worn.

The operation, in which I was assisted by Drs. J. W. Elliot, Russel Sturgis, and J. H. Richardson, lasted about an hour and a half. It was done under the carbolic spray. The abdomen was opened along the line of the former ovariotomy incision; there were some elastic adhesions between the bowels and the cicatrix; and many small round hard nodules (cancer) were felt scattered about in the peritonæum. By careful search I could find no band, nor any adhesion, but at length I found the point of obstruction to be in the descending colon just above the sigmoid flexure. It was a hard (cancerous) mass which filled the calibre of the bowel and produced a linear cicatricial looking stricture. It was impossible to excise this part of the bowel, for I could not drag it up above the pubes sufficiently to enable me to sew the divided ends of the intestine together (and, indeed, I did not feel hopeful enough of success to have attempted the excision even if I could have done it). Accordingly I asked Dr. Elliot to grasp the bowel firmly above the obstruction high enough to enable me to open it above the stricture and to sew it to the skin in order to make an artificial anus in the pubic region at the very lowest point of my incision just behind the bladder.

To Dr. Elliot's careful manipulation the success of the operation was largely due. After I had completed the attachment to the skin, I surrounded Dr. Elliot's hand with sponges and towels within the abdomen, and held the opening as much outside the abdominal cavity as I could. Dr. Elliot then released his grasp, and enormous quantities of semi-solid fæces of a yellow color, mixed with gas, ran out over everything, the patient, the table, the rubber sheet, and the floor. We all thought that some of this ran into the abdominal cavity, indeed we were pretty sure of it, but we did our best to prevent it. The abdominal wound was then sewed up and dressed antiseptically, but this was of no use, as the intestinal contents soon overflowed and soiled everything in the neighborhood. After several cleansings and washings there occurred a pause in the intestinal flow, and we placed the patient in bed. The dressings were changed four times in the next

[1] Read before the Surgical Section of the Suffolk District Medical Society, December 5, 1883.

twenty-four hours. At the last dressing the discharge was found to be mucous in character.

At 8.30 P. M. a subcutaneous injection of one eighth of a grain of morphia was given for pain, and the patient passed a very quiet night. Milk and liquid food were given in small quantities and retained. The discharge from the artificial anus continued to be colorless mucus of a very offensive odor for the second twenty-four hours, and no fæcal matter was seen. In a few days more she was eating solid food. The bowels gradually became pretty regular, moving sometimes twice and sometimes four times a day, and the discharges became fæcal and solid as in health. The temperature ranged between 99° F. and 101° F. for the first fortnight, and rose on the 5th of January, 1882, to 103° F. for the temperature and 115 for the pulse respectively, owing to a little pus in the wound. From this time her recovery was uninterrupted except by a slight attack of diarrhœa on January 22d. The nurse wrote on January 13th: "The patient sits up every day for four or five hours, and to-day she walked across the room twice with my assistance. The opening is very easily managed by putting in a plug of cotton, over that folded compresses, then a roller bandage tightly applied, and over all a tight swathe. When she goes to bed for the night it is dressed more loosely to allow the contents of the bowel to escape."

When she had entirely recovered and could take care of herself Dr. Codman fitted a hard-rubber pad with a movable joint to the artificial anus, and this kept the opening closed except when, as sometimes happened, there was diarrhœa. Mrs. R. enjoyed herself and was happy during the summer of 1882, but she never went about in society at all, as she found it impossible to control the discharge of flatus from the artificial opening. When I asked her if her physical condition made life a burden, she said, "Not at all; I am perfectly comfortable, and can accomplish all I want to. If you have any patient in the condition I was send her to me and I think I can convince her that I am much better off than before the operation, and except that I don't like to go among people, I suffer very little inconvenience."

As I have quoted largely from Dr. Richardson's letters, I will add that he told me that there was no trouble in the evacuation of the bowels from the beginning to the end, and that one could hardly believe that an artificial anus could make so little trouble. All this time, however, the different cancerous deposits in the abdomen were growing, and by the latter part of the autumn one mass reached from the site of the wound to the epigastrium. Mrs. R. gradually failed, and died October 10, 1882, ten months after the bowel had been opened.

There was no autopsy.

The second case of exploratory incision to ascertain the cause of intestinal obstruction occurred in the practice of Dr. A. H. Nichols, of this city. I give the history of the case previous to the operation in his words:—

"On the 1st of June, 1882, I was called to Mrs. T., and found her suffering from obstinate constipation of three weeks' standing, though she did not complain of any especial inconvenience arising from this suspended function. She was apprehensive, however, that this constipation might be an indication of intestinal cancer, a trouble said to be hereditary in her family. She was able to recall the history of three members of her family who had died from this disease, and she remembered that in two of these cases constipation was the first and prominent symptom. It was, furthermore, firmly impressed upon her mind that in these two cases there existed little or no suffering until the administration of powerful cathartics by the advice of the physician. She accordingly stipulated that no laxatives should be ordered in her own case. I saw no reason for sharing her forebodings, and attempted to relieve her constipation by means of frequent laxative enemata, which proved utterly inefficient, though some encouragement was derived from an insignificant dejection at the expiration of about a week, but with this exception no fæces whatsoever were voided. Until about the 22d of June the ordinary signs of intestinal obstruction — pain, nausea, retching, distention, tumor, quickened pulse, elevated temperature, etc., etc. — were all absent. The most that could be made out was a somewhat increased fullness of the bowels, more noticeable in the right iliac region. On the 23d of June this abdominal fullness had increased, but was not especially prominent at any one part, and during the following night she complained for the first time of colic, which was not severe enough to call for any opiate. During all this period she went to the table, and was allowed a limited quantity of simple nutritious food. After the consultation with Dr. John Homans on the 23d of June she was informed that there existed an intestinal obstruction which could not be relieved except by surgical interference, and she was fully warned of the danger and uncertainty attendant upon any such operation. This unfavorable announcement was received by her with fortitude and equanimity. She remarked calmly that her original prediction was verified, and after a brief reflection decided to submit without delay to the operation proposed (colotomy) rather than to wait for the supervention of any further complication. On the evening of the 23d she rode in an open carriage to my office, and proceeded thence to the private hospital selected for the operation."

The operation was done on the 25th of June, after seven weeks of complete obstruction of the bowels. The patient, a fleshy woman, looked worn and anxious, and was in great pain. The abdomen was much distended with gas. I may remark that the day was intensely hot, the thermometer registering, if I recollect right, 93° F. As Dr. Nichols thought there was an accumulation in the right iliac region, and as neither of us knew exactly where the obstruction was, I deemed it best to make an incision in the neighborhood of the right linea semilunaris. The operation was done under the carbolic spray, and with every antiseptic precaution. Encouraged by the result of the previous case I hoped for a favorable issue. My first incision was three inches long, and was made through the external oblique muscle, and just beyond the outer border of the rectus. Two branches of the epigastric artery were cut and bled freely; these were tied before the peritonæum was opened. When the peritonæum was divided great care was taken not to wound the omentum, which presented itself spread out over the small intestines. The omentum was pulled gently out of the wound and divided and tied because it was adherent below beyond the cæcum. If I separated it from its adhesions below the cæcum I feared that I could not control the hæmorrhage, and if I did not either separate it or divide it I could not get in my hand to explore the interior of the abdomen, conse

quently I tied it above and below, and divided it between the ligatures. The opening in the abdominal walls was, however, too small for manual exploration, and the incision was extended upwards. The bowels, large and small, were greatly distended with wind, and in some places were of a deep-red color, but had not lost their shining lustre. The exact seat of the stricture was hard to find out. I thought I felt a constriction in the descending colon in the left lumbar region, and as this was below the cæcum I determined to make an artificial anus in the cæcum. The abdominal cavity was, therefore, carefully sponged out, and an incision about three quarters of an inch long was made in the cæcum, and the edges of this opening were carefully stitched to the parietal peritonæum and to the skin. Great care was taken that none of the fæcal contents should enter the abdominal cavity. I placed nine soft sponges around the cæcum, and Dr. M. H. Richardson and F. B. Harrington succeeded perfectly in preventing the entrance of any fæces while I was passing the sutures. Much embarrassment was occasioned by the great distention of the coils of intestine, and it would have been better to have made the opening quickly without searching for the seat of the stricture; however as the obstruction might have been from a band or a twist it was natural that I should have sought for it. The operation was a long one (an hour and a half), and the weather was intensely hot. When the patient was placed in bed her pulse was rapid, but she was otherwise in fair condition. Wind and fæces came out through the opening in the cæcum. Hot bottles had been put at the patient's feet, and I left her in charge of Dr. Nichols. The following is his farther account of the case: —

"Directly after the operation a copious discharge of semi-liquid fæces set in. Upon coming out of the ether she complained of great pain, and was extremely restless. Her pulse soon showed signs of weakness, and she succumbed to the effects of general shock five hours after the conclusion of the operation, the severity of her suffering during the last two hours requiring a resort to ether.

"At the autopsy, made by Dr. W. P. Bolles, the same evening, there was found an annular cancer (scirrhus) in the descending colon, about eighteen inches from the orifice of the rectum, occluding the intestine so completely as to prevent the flow of even water. Below the stricture the intestine was completely empty. Above there was found small, scattered masses of fæces, but the great bulk of the contents had been expelled from the artificial opening. There existed no signs of inflammation of the intestine above the seat of the stricture."

It will be seen that the result in these two cases was different, but in both the operations adopted were logical and proper. In the second operation there was much more handling of the bowels than in the first, and it was very difficult to manage the insertion of the sutures and to keep the bowels from protruding between them or being wounded by the needles. I believe that Mr. Lawson Tait thinks it better surgery to open the bowel at any point you happen to strike (that is, to pull out the first loop that presents itself and open it) than to search for the obstruction. In our second case that mode of proceeding would have been the best. I present these two cases to the Society as a contribution to the study of the treatment of intestinal obstruction.

THE TREATMENT OF RETAINED SECUNDINES AFTER ABORTION.[1]

BY JOHN W. BRANNAN, A. B., M. D., OF COLORADO SPRINGS.

THE management of incomplete or imperfect abortion has excited renewed interest and discussion during the past year. The gynæcologist on the one hand and the general practitioner on the other have expressed their respective views with much warmth and earnestness of conviction. The gynæcologist insists upon the immediate removal of the retained membranes and placenta by manual or instrumental means; the general practitioner, while admitting fully the desirability of the complete emptying of the uterus, believes that this is nature's task, and that the physician should not interfere unless the symptoms are urgent. The former fears the present risk of hæmorrhage and the future risk of septicæmia; the latter fears inflammation as a result of uterine manipulation. Such is a brief statement of the points at issue between the disputants.

Let us suppose, for example, a case of abortion at the third month of pregnancy; the fœtus has come away, the secundines are retained, the cervix uteri is more or less contracted, the woman is comfortable, there is no hæmorrhage or offensive discharge. The gynæcologist would at once proceed to extract the membranes and placenta, using the finger, curette, or forceps, according to the state of the cervix; if the cervix is tightly closed, he would dilate it with tents or metallic dilators, and then extract as before. The more conservative general practitioner, however, would preserve an expectant attitude, contenting himself with giving full doses of ergot, and possibly tamponing the vagina; should alarming hæmorrhage or symptoms of septicæmia supervene he would then, but not before, feel called upon to empty the uterus in the manner described above.

On consulting the obstetrical literature of the last twenty-five years we find the same difference of opinion that now exists in the profession. The earlier writers of this period, however, are agreed in advising the expectant treatment of retained portions of the ovum. Tyler Smith[2] and Bedford[3] assert that in such cases there is not the same tendency to decomposition and its dangers that there is in the case of placenta at full term. Meigs[4] prefers to leave such occurrences in the hands of nature, and believes that there is no danger in so doing. Ramsbotham[5] relies upon the vaginal tampon and the use of ergot when the membranes cannot be reached with the fingers in the vagina. Hodge[6] says that "the extraction of the retained membranes certainly ought not to be attempted by manual or instrumental measures if there be little or no bleeding, especially as the os and cervix generally contract, and the membranes are closely adherent." Churchill[7] believes that we are not to interfere when the membranes are retained, unless there is hæmorrhage or evidence of irritative fever. He concludes as follows: "Larger experience has made me less fearful of leaving these cases to nature, and more unwilling

to interfere hastily." Leishman[1] advises us to preserve an expectant attitude if the membranes are retained, unless the hæmorrhage be alarming. In the latter case he tampons the vagina. While admitting the danger of blood-poisoning from a putrefying retained placenta, he adds that such poisoning is rare.

We now approach the period in which modern gynæcology has made its greatest advances, and its influence upon its kindred branch of medicine, obstetrics, is at once seen. The more a given writer is occupied with gynæcology and the less with the general practice of medicine the greater is his activity in interfering with the processes of nature. Barnes[2] says that the first indication is to "empty the uterus." If the os is open he at once removes the whole ovum with the finger, breaking up the decidua if necessary. If the os is closed he immediately dilates the cervix with laminaria tents, and then removes the membranes with the finger as before. He does not use ovum forceps. He condemns the vaginal tampon as "unscientific and illusory," claiming that it neither stops the hæmorrhage nor favors the dilatation of the cervix. Playfair[3] tampons the vagina and gives ergot in cases of alarming hæmorrhage or of undilated os uteri. If the os still remains closed he employs sponge tents for its dilatation, even though there be no urgent symptoms. He then removes the ovum with the finger. He admits, however, that "cases are frequently met with in which any forcible attempt at removal would be likely to prove very hurtful, and in which it is better practice to control hæmorrhage by the plug or sponge tent, and wait until the placenta is detached."

Prof. A. R. Simpson[4] blames the authors of our obstetric text-books for failing to state clearly how we can best secure complete evacuation of the uterus in cases of abortion. He advocates the use of a sponge tent, previously disinfected, as soon as the abortion appears unavoidable. He also gives ergotine hypodermically. When the cervical canal is dilated he removes the ovum from the uterus with the fingers. In order to render the uterine cavity accessible to the exploring finger he either pushes down the fundus uteri from above or drags down the cervix from below with vulsellum forceps. He deprecates the use of instruments for the detachment of retained portions of the ovum.

Schroeder[5] employs the tampon if the hæmorrhage is alarming or the ovum is retained. He claims that the tampon always checks the hæmorrhage, and as a general rule effects the expulsion of the ovum from the uterus. In case some portions of the ovum are still retained by a contracted os, he dilates the cervix with sponge or laminaria tents, and then empties the uterus with the fingers. If any placental fragments cannot be reached by the hand he employs forceps for their extraction.

Angus Macdonald[6] is more conservative than the four preceding writers. He says: "My opinion, therefore, is that in the ordinary run of cases, in which the hæmorrhage is not specially profuse, we ought to trust to ergot by the mouth, or ergotine subcutaneously, and that we shall most probably find that all will go on all right, except that we shall have to hurry the conclusion of the case with slight manipulation, and that wholesale imperfect plugging of the vagina is to be strongly deprecated." If, however, hæmorrhage is severe, or symptoms of septicæmia arise, he takes "active measures to empty the uterus *tuto, cito, et jucunde*." If the os is open he removes the uterine contents with the fingers. If the os is closed he introduces a sponge tent and leaves it in situ from two to four hours. He then clears out the uterus, as before, with the fingers. Macdonald opposes the use of abortion forceps for the removal of the membranes, and also considers it an unnecessary and dangerous procedure to drag down the cervix with a vulsellum, as recommended by Simpson.

Lusk[7] endeavors to empty the uterus as soon as possible. If the cervix is patent he removes the membranes from the uterus with the finger. If the cervix is closed he employs the tampon, giving it three trials, each tampon being left in the vagina for twelve hours. If, after the removal of the third tampon, the cervix is still undilated, he resorts to sponge tents. He prefers to use the tampon before the sponge tent, as the former stimulates the uterus to contract, and promotes the separation of the membranes, even when it fails to secure their discharge. Lusk fears the results of putrid decomposition of the retained placenta. At the same time he admits that "fatal results are rare, as decomposition is usually a late occurrence, setting in, as a rule, only after protective granulations have formed upon the uterine mucous membrane, and after the complete closure of the uterine sinuses.

T. Johnson Alloway,[8] of Montreal, agrees with Simpson in his criticism of text-books on obstetrics because in them "insufficient stress is laid upon the importance of removing at once a retained placenta after abortion." He himself advocates the immediate removal of the secundines with the curette, not the finger, either with or without previous dilatation of the cervix. He maintains that, as a rule, it is impossible to remove the membranes with the finger unless the uterus is forced down in the pelvis to a dangerous degree.

Dr. Mundé[9] gives it as his opinion that "the future safety of the patient demands that the secundines should be at once removed after expulsion of the fœtus in every case of abortion in which such removal can be accomplished without force sufficient to injure the woman." His manner of operating is as follows: If the cervical canal is sufficiently patulous he detaches and removes the placenta with the fingers of the right hand while crowding down the fundus uteri with the left hand. If, however, the abdominal walls are fat or tense, or if the cervix is not sufficiently open to admit the finger easily, he employs the curette and placental forceps for the detachment and removal of adherent portions of membrane. The uterus is then washed out with a two to five per cent. solution of carbolic acid, the water used being either very hot or very cold. If there is the slightest suspicion of septic infection he swabs out the uterine cavity with pure tincture of iodine. Should the cervical canal be too narrow to admit even the curette it is at once dilated by the tupelo tent. Mundé prefers the tupelo to the

[9] Ibid.

sponge because, although he himself has never met with an accident from sponge tents, he is "afraid to incur the risk of adding another to the *many examples of septic infection from that agent.*" (Italics mine.)

Mundé asserts that all this manipulation is so free from danger that every physician can employ it, and that the risk possibly incurred from letting the secundines alone is greater than that from their forcible removal. He gives a table of cases seen by him, in which he removed the secundines fifty-seven times by fingers and curette with but one fatal result. The length of time of retention of placenta was less than one day in eighteen, one day to one week in thirty-three, one week to two months in six, cases.

Dr. W. H. Farr [1] is in favor of the immediate removal of the membranes after abortion. He employs the curette forceps, and opposes the use of the finger as being dangerous. He writes: "I have one case in mind in which a physician of experience removed by the finger the retained product of abortion. The woman said the pain he caused was agonizing, and she was left the victim of prolapse of the uterus and a long train of nervous manifestations." Farr also refers to the dangers incident to dilatation of the cervix.

Dr. Walter Coles,[2] of St. Louis, opposes the immediate removal of the membranes as a matter of routine in every case of abortion. He believes that each case should be treated according to its indications. If the immediate symptoms are urgent the placenta should be at once removed by the finger, forceps, or curette, the cervix having been previously dilated if necessary. If there are no urgent symptoms the expectant plan should be pursued. It is his opinion that inflammation, the result of rough manipulation of the uterus, is much more to be feared than either hæmorrhage or septicæmia. Dr. Coles's paper was read before the St. Louis Obstetrical and Gynæcological Society. A general discussion followed, and it was evidently the sense of the Society that the expectant plan is safer than the immediate removal of the secundines by manual or instrumental means.

From the foregoing extracts it is seen that dilatation of the closed cervix with tents and extraction of the secundines with the finger or forceps is the usual method of procedure of those who advocate the immediate removal of retained portions of the ovum. Mundé claims that this manipulation is so free from danger that every physician can employ it. If this be true it is a strong argument in favor of active interference.

Dilatation of the cervix uteri with tents is the first step in this manipulation. Thomas [3] writes as follows with regard to this operation: "There is always danger in dilating the cervix by tents, though it is by no means so great as to make one hesitate in employing them, for the cases which demand them are often urgent ones, and they serve a purpose not attainable by any other means. It is much to be regretted that practitioners have not shown more alacrity in publishing unfortunate results from the use of this method of exploration and treatment. Had all the fatal cases which have resulted from accidents due to tents been faithfully recorded the list would now be a long one, and it would be greatly lengthened by a record of all the instances in which tedious, exhausting, and dangerous disease has thus been excited. . . . In my own practice I have met with four fatal cases resulting from the use of tents. Besides these I have seen, as every other gynæcologist has who has employed this means to any extent, a number of cases in which the following affections have been excited by them: pelvic peritonitis, peri-uterine cellulitis, septicæmia, endometritis, and hæmatocele. This is the record of my own practice, and my observation of that of many of my friends whose results I have an opportunity of seeing exactly agrees with it. Dr. Braxton Hicks says: 'I have seen a case end fatally where there had been dilatation a week previous, mental shock suddenly lighting up the inflammation and extending it to the peritonæum.'" Mundé himself fears sponge tents because of the many examples of septic infection due to them. He therefore uses tupelo, the newest material for tents in favor with gynæcologists. Fritsch,[4] however, asserts that "laminaria and tupelo will disappear just as sponge tents have vanished." He criticises severely the routine dilatation of the cervix uteri that is now so general among gynæcologists, and says that he himself has given up tents altogether, and has no cause to regret it.

It appears, then, that the first part of Mundé's manipulation is attended with danger. Let us now consider the extraction of the membranes by the finger, curette, or forceps. Barnes, Playfair, Simpson, and Lusk of the advocates of active interference deprecate the use of the curette or forceps as being hazardous. They employ the finger, and consider it safe and satisfactory. Alloway and Farr, on the other hand, regard the use of the finger as highly dangerous, and claim that the curette gives better results. We thus have testimony from the gynæcologists themselves that the forcible extraction of the secundines, whether manual or instrumental, is not free from danger.

Having shown that active interference in imperfect abortion is a dangerous procedure, we have now to inquire into the necessity of the operation. If the placenta does not soon follow the fœtus or is not forcibly removed what happens in the majority of cases? Published statistics on this point would be valuable and interesting, but, unfortunately, there are none. We must rely upon our individual experiences for an answer to this question. I think that practicing physicians will bear me out in the assertion that the great majority of these cases take care of themselves or at least require but little assistance from us. The placenta comes away in the next twenty-four hours, or within a few days, or at the next menstrual period. By far the larger proportion of abortions, as of deliveries at term, fall to the care of the general practitioner, the family physician; only a very small percentage reach the gynæcologist in the first instance. The latter sees the exceptional cases, the cases which have resulted badly, and therefore seek his special skill.

As illustrations of the course ordinarily taken by those abortions in which the ovum is not expelled entire I shall here give brief notes of three cases which have occurred in my practice: —

Case I. March 11, 1880. Mrs. O., multipara, aged thirty-two years. Catamenia ceased three months ago. Shifting pains in back and hips for last three days; slight flowing yesterday, increased to-day; uterine pains for several hours. A ten weeks' fœtus found lying in

[4] American Journal of Obstetrics, February, 1883.

vagina and removed. Placenta could be felt within internal os. No hæmorrhage or discharge. Pulse 120; temperature 102° F. Treatment, one drachm of extr. ergot. fl. and one sixth grain morph. sulph. subcutaneously.

March 12th, A. M. No change in placenta. Pulse 72; temperature 98° F. Ergot and morphia as yesterday. P. M. Placenta still felt within os; hæmorrhage slight. Pulse 96; temperature 99.5° F. Swept my finger once around the circumference of the internal os, between it and the placenta, otherwise no manual interference. Ergot and morphia continued.

March 13th, A. M. Was told that placenta had come away twenty minutes after my visit of preceding evening. Pulse 90; temperature 98.5° F. Patient made rapid recovery.

CASE II. July 25, 1883, six A. M. Mrs. M., multipara, aged twenty-six, four months advanced in pregnancy. Occasional pains in back for last two weeks, with considerable flowing. Lost much blood yesterday, and early this morning a solid mass came away. A four months' fœtus, somewhat macerated, found in the basin. No placental fragments. Examination showed the placenta to be still within the uterus, the os being closed firmly around the umbilical cord. No hæmorrhage. Temperature and pulse normal. Twenty minims of laudanum and one drachm of ergot given. At ten A. M. vagina carefully tamponed with wads of cotton soaked in glycerine. Ergot repeated. Six P. M. Tampon removed and vagina washed with two and a half per cent. solution of carbolic acid. No change in state of cervix. Ergot and laudanum repeated.

July 26th. No change. Tampon again used, removed in evening. Ergot and laudanum continued.

July 27th. No change. Tampon omitted. Ergot and laudanum continued. Vaginal injections of two and a half per cent. solution of carbolic acid to be given twice daily.

July 28th. No change. Medicines omitted.

July 29th, P. M. Placenta expelled entire, no offensive odor whatever to it. Rapid recovery.

CASE III. August 20, 1883. Mrs. W., multipara, aged forty-seven years. Sufferer from repeated abortions since twenty years of age. Menses ceased ten weeks ago, patient supposing that she had reached the climacteric. Has not felt well for a week. Yesterday had pain in back, and slight flowing. This morning severe bearing down pains, and passed large amount of clots, together with fœtus and after-birth in fragments. Patient thinks that everything has come away. Nothing found on examination except a hard cervix fissured in various directions, with os tightly closed. Uterus appeared to be about normal in size. Fifteen minims of laudanum and one drachm of ergot given twice daily and carbolized vaginal injections. Nothing of note occurred in the case until August 22d, two days after the abortion, when at my usual visit I was shown a fragment of placenta, about one and a half inches in diameter, which the patient said had been expelled that morning. The mass had scarcely any perceptible odor. From this time on the patient progressed rapidly to perfect recovery.

The above cases caused me no little anxiety at the time of their occurrence. Their fortunate termination, however, would warrant me, I think, in pursuing the same course in similar cases in the future.

We know and may admit freely that the retained placenta does occasionally give rise to hæmorrhage or to symptoms of septicæmia. Mundé's own cases, however, show that forcible removal can even then be effected with good results. In fifty-four of his fifty-seven reported cases the placenta had been retained for a period varying from a few hours to two months. And yet recovery of the patient followed the removal of the placenta in all but one of these cases. On this point Muratoff,[1] of Moscow, who employs Sims's uterine dilators in all cases of neglected abortion, expresses himself as follows: "The presence of inflammation in the uterus or in its vicinity does not contraindicate the use of metallic dilators; on the contrary, it vitally indicates instrumental dilatation. In the great majority of my cases, dilatation, with subsequent emptying of the womb, was immediately followed by a marked improvement both of the local and of the general conditions; the patient's temperature steadily and quickly fell to the normal level, rigors and pain disappeared, the uterine discharge rapidly lost its offensive odor, and the uterus underwent uninterrupted involution." Muratoff, after dilating the cervix, does not at once introduce the curette or forceps or the hand into the uterus. He first tries bimanual expression of the uterine contents. Should this fail, the membranes are removed by one or two fingers. Besides Mundé's cases, I have collected thirty-two other published cases of forcible removal of long-retained placenta (one retained for 115 days, another for six months), and in all of them the patient recovered. We thus have a total of eighty-six cases, with but one death. Would the fatality be as small if physicians, however lacking in technical skill, were to proceed to dilate and extract in every case of abortion as soon as the placenta showed a tendency to delay?

Having argued to prove that active interference in abortion is as a rule unnecessary and dangerous, it follows that I agree with those who favor the expectant plan of treatment. This does not mean, however, that abortions should be "neglected," as the gynæcologists express it.

The following outline of treatment would seem to me judicious, and as answering all the indications in a case of abortion in which the secundines are retained after the expulsion of the fœtus: If the membranes are lying loose in the open cervix, they should be removed by the finger. If, however, they are still within the cavity of the uterus, no attempt should be made to remove them, whether the cervix be open or closed. Full doses of ergot should be given, and the vagina should be carefully tamponed. The ergot and tampon will check whatever hæmorrhage there may be, and will also serve to excite the uterus to contract and thus effect the separation of the membranes. Two or three tampons may be used, each being le ftin situ about twelve hours. The vagina should be well washed with a two and a half per cent. solution of carbolic acid at each removal of the tampon. If the membranes still remain within the uterus, and there be no hæmorrhage or evidence of blood-poisoning, we may leave the case to nature, merely continuing the ergot and carbolized vaginal injections for a few days. Besides enjoining the rest usual after all abortions, the physician should keep the patient under observation for a few weeks, if possible. If at any time serious and repeated hæmorrhages should occur, or symptoms of septicæmia should manifest themselves, these steps should be taken to

[1] London Medical Record. The Medical Gazette, December 1, 1883.

empty the uterus at once. If the cervix is patulous, bimanual expression of the placental remains should be tried. If this fails, the fragments may sometimes be brought away by intra-uterine injections. Last of all, we may resort to the use of the finger or the curette and forceps. If the cervix is closed, it should be dilated with the tupelo tent or Sims's dilators, and the uterine contents then removed as before.

Therapeutic Memoranda.

AN OVERDOSE OF CHLORAL.

BY JOHN P. REYNOLDS, M. D.

To a young and healthy patient in third labor, with a good presentation of the head, I gave, as I supposed, three times, at intervals of fifteen minutes, a dose containing fifteen grains of chloral. I had no better motive for its administration than the hope of comforting the patient, who was making moderate complaint. I shortly discovered that in forty-five minutes I had given her a hundred grains, and for the hour and a half which ensued I watched her condition with no little uneasiness.

She grew drowsy and heavy. The progress of the labor gave her no farther concern. If addressed, she could be roused to make answer, but soon fell off again. The pains became slow and ineffective. The pulse was at between sixty and seventy, full and laboring. Her hands, held by her husband looked almost black under his pressure. Fifteen minutes after the third dose of chloral I ruptured the membranes; and twenty-five minutes later, not quite two hours from the first appearance of pain, a male child was slowly extruded into the world. The surface of the child was excessively pale, and from head to foot it was besmeared with meconium. After very moderate efforts, however, it began to breathe and cry; but it did not for several hours regain its natural color. The placenta was soon expelled, though without any portion of the membranes. One drachm of fluid extract of ergot was twice given, and a half ounce of brandy. An hour after the birth the mother was in fairly good condition, and both she and thec hild made a safe recovery.

If now I add, that it would be hard to name husband and wife more widely known in the community where this occurred, or more deservedly admired and honored, I may emphasize for some readers the story of personal distress.

— The *Edinburgh Medical Journal* highly recommends for the ordinary eczema of the head in children, so commonly met with in dispensary practice, after two or three thorough cleansings, the daily application of the following salve: —

℞ Acid. salicylic. . . . . gr. x.
Tinct. benz. . . . . ℥xx.
Vaselini . . . . . ℥i.
M. ft. ung.

On other parts where a soft, easily melting salve such as this is not suitable, or where a firm dressing or a drying effect is desired, the following paste should be rubbed on: —

℞ Acid. salicylic. . . . . gr. xix.
Vaselini . . . . . ℥i.
Zinci oxidi, amyli . . . . . aa. ℥ss.
M. leniter terens, fiat pasta.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

IN MEMORIAM. — DR. CALVIN ELLIS.

January 9, 1884. The meeting was called to order at eight o'clock, Dr. R. T. Edes in the chair. A summary of the proceedings of the last meeting was given by the Secretary.

Upon motion of Dr. George B. Shattuck the business of this meeting was suspended as a token of respect to the memory of the late Dr. Calvin Ellis, formerly President of the Suffolk District Medical Society.

Dr. Edes, in announcing the result of the motion, made some very appropriate remarks relating to his early acquaintance with, and life-long esteem for, Dr. Ellis, a man whose character would long be a living influence in the medical element of Boston. Dr. Edes then called upon Dr. George C. Shattuck, who spoke as follows: —

Dr. Shattuck said that he could not refuse an invitation to say a few words at this time, and to bear his testimony to the worth and excellence of our late associate, Dr. Calvin Ellis. It certainly is well for us survivors, after the departure of a highly esteemed associate, to meet together and put on record our appreciation of worth and skill and our sense of loss. Excellence and distinction in our profession are the result of original endowment, of industry in training faculties, in acquiring knowledge, and of fidelity and skill in the discharge of duties. A medical man must devote years to preliminary education, and then must be constantly studying and training his powers of observation and reasoning, as well as adding to his stores of knowledge. There are those here who were associated with Dr. Ellis in his early years and will tell us of the qualities for which he was remarkable as a young man and a student. I became associated with him when he had already acquired reputation as a teacher and practitioner, and was looked upon as on the sure road to distinction. I noticed, and admired, his knowledge and skill as the pathologist of the Massachusetts General Hospital and instructor in clinical medicine in the Medical School. His ability, knowledge, and fidelity were recognized by professors and students. He was evidently the coming man in his department. And yet he worked patiently in subordination, was always kindly and courteous, and ready to carry out the plans of those who had the direction of affairs. When his predecessor in accordance with his own wishes and ideas of duty retired, Dr. Ellis was chosen professor of clinical medicine and visiting physician of the hospital, without any solicitation on his own part or from his friends, but because those who had the appointing power recognized that he was the fittest man to discharge the duties. The wisdom of the appointment was shown by many years of successful work. And when obliged by painful illness to retire from work, those who appointed him, those who worked with him, and those for whom he worked, preferred to wait for three years in the hope that his health and strength might be renewed so that the same skilled labor might still be at the service of medical science and instruction.

These hopes have been disappointed. He who knows what is best for each and all of us has removed him. We must acquiesce in this decision, whilst we may cherish the example of conscientious devotion to duty, of scrupulous regard to the rights and feelings of associates, of self-sacrifice in ministering to the sick and the poor, and in efforts to teach the young and the ignorant. May we all be able to profit by his example, so that when to each of us the summons to depart comes, the plaudit, "Well done good and faithful servant," may be on the lips of our survivors.

The Secretary then read the following letter from Dr. HENRY I. BOWDITCH: —

January 9, 1884.

To the Secretary of the Section of Clinical Medicine of the Suffolk District Medical Society: —

DEAR DR. BLODGETT, — I am very sorry that I am at present confined to the house, and shall therefore be unable to be at the "Memorial Meeting" which is to be held by the Clinical Section of the Suffolk District Medical Society at its first meeting after the death of our friend, Dr. Calvin Ellis. The Section, in which he so long labored, acts most appropriately in proposing to have this "Memorial Meeting."

Dr. Ellis has just died, after a long and distressing illness, which he bore without complaint and with a manly fortitude, while, however, looking forward hopefully, as was his nature, to its ultimate result, because it was non-malignant.

He was my pupil in his days of medical study, my assistant at the Massachusetts General Hospital, and afterwards my successor there, and also in the Professorship of Clinical Medicine at Harvard University; and, finally, he was always a most beloved friend. For many years past I have often sought his advice, and no one that I met gave wiser counsel than he did; for his words were uttered only after a most rigid examination of the matter in hand. To me his loss is simply irreparable; for no one can fill another's place.

But I do not write this in order to praise him or to mourn for his loss. His own life is his highest praise; and the termination of the earthly career of a really noble soul has not a particle of sorrow connected with it, which is not far outweighed by a kind of satisfaction, not to say joy. The beauty of Dr. Ellis's everyday life from the cradle to the grave seems well rounded out by his serene, uncomplaining death. If with this death we remember the years of almost hopeless and severe suffering so sweetly borne by our friend, then Death has no horrors, but comes rather as an angel of divine mercy to the relief of suffering humanity.

If by his intellectual acts a man has left, as Dr. Ellis has surely done, his impress for good upon hundreds who have either sought his instruction, or have met him in the daily walks of life, then the natural sorrow which we must feel for his loss is wonderfully mitigated; and he becomes forthwith a silent, but not less effective, exemplar, to all who knew, loved, and respected him. And where is there one who intimately knew Dr. Ellis who did not love and respect him?

Since his death I have been led to inquire into the antecedents of his family and of himself before we became personally acquainted, and I have been interested and instructed to find how many of his more striking moral and intellectual traits he owes to heredity. I shall give, of course, only a glimpse of the facts, because my purpose, on the present occasion, requires nothing more.

Two hundred years ago, or thereabouts, his earliest progenitor in this country came here from the ranks of the hard-handed independent-souled yeomanry of England. He settled in Dedham, Mass., and there tilled his acres and reared his family. A home on the site still stands, and it is occupied, as it has always been, by one of the same stock and name. Calvin Ellis, our deceased associate, was the seventh descendant from this first settler. It would seem that as the generations have passed along, work, solid work, and a belief in the real excellence and nobility of work, has been ever a prominent trait among all his ancestry. But there was with it also a love of culture, so far as that was possible in the earlier times. The Ellis family has given clergymen, physicians, lawyers, and energetic merchants and many honorable and excellent men and women to the world. His grandfather brought up a family of eleven children, and, aided by the thrift and economy of his wife in her wise management of his household, left as the net result of their joint lives $30,000 for their heirs! Surely here was a trait of energy, physical and intellectual, worthy of commendation. This same grandsire believed so strongly in work that he had a contempt for the bare idea of a man's having "nothing to do." His favorite expression was, "I would rather my son should throw stones from one heap to another, and then throw them all back again, than have 'nothing to do.'"

Again, fully believing in the excellence of the intellectual, as well as the physical training of any youth, he had his youngest son prepared to enter Harvard.

Unfortunately, as the story goes, the youth was by his brothers fairly laughed out of trying a college life.

Dr. Ellis's parents moved into Boston before his birth, and the father, Luther Ellis, became an energetic and successful iron merchant. Retiring from active business with a property ample for his wants, he had his son Calvin, our associate, educated for Harvard. Both parents have left loving memories of themselves in the hearts of their children, and of others. Their home, as the story comes to me, was one of those delightful places where parents and children mutually loved and respected and helped one another.

Religion, too, was taught in and governed it. The boys and girls went in their earlier days regularly to church. They were not governed by tales of terror as to the future, but were led to honorable thought and action rather by the examples of loving kindness and of independence of thought given to them by their parents.

They were styled Unitarians, a term of obloquy formerly, less so of late, since science has tended to break down sectarianism, that stronghold of the devil. The mother who presided over the domestic affairs had a gentleness and firmness of purpose, combined with a bright, contented, and self-sacrificing spirit. Her example proved to the children the lovableness of these qualities. The father, after long suffering borne with exemplary patience, died during the first year of Dr. Ellis's college life. Thus we see that while receiving from his earliest ancestors the fine manly traits of love of work and of liberality and independence of thought, with a desire for culture of the intellect, so far as was possible, his parents left him also a legacy of sweet and winning traits, that shone so conspicuously, during all the years of our friend's life.

As a boy he was of a quiet character, less boisterous than most boys of this age. He was, however, intel-

ligent and bright, and a favorite with all who knew him. His college life was uneventful. He was an athlete, and was in the first boat's crew ever organized at Harvard. He took no very high honors, but he faithfully did his allotted tasks. Upon entering the Medical School, he used to say, he first awoke to his life's work, as play had been his object during his college days. He became earnest and was ever at work, to do what the hour called him to perform.

When I met him as an assistant he had no flourish or pretense or servility about him. He was always deferential, but not crouching submissively to me, or any one, though cheerfully undertaking what was imposed upon him by his superiors. He rarely, if ever, failed in the due performance of the task; always had that bright yet dignified manner which he subsequently bore in his professional career. In his meetings with you, his associates, I am sure you always found him simple, thorough, and true. When dealing with a professional associate he needed no "Code" of by-laws to keep him fair and honest. His own well-balanced mind and generous spirit forbade him to do anything to injure a brother physician's reputation even in the smallest degree.

To do so by a word, a covert sneer, or even a smile of doubt in the presence of by-standers, as is done at times, by some of the stoutest defenders of the "*Code*," he abhorred. I shall never forget the glee (for, among other good qualities he heartily enjoyed a joke) with which he told me, only a few months ago, how he and others had *squelched* instantly a proposition coming from a committee of the Counselors of the Massachusetts Medical Society, a proposition, which, had it been adopted by the Society, would have violated one of the prime rules of common courtesy, and even those of simple hospitality in many of our country villages and small towns.

As a teacher of medicine I need say nothing, as most of the younger men of this Society must have known him well in that capacity. His object was to teach a student the methods that should be pursued in order to come to a perfect diagnosis. I was much struck with the remark made by one of the juniors of our profession, when I asked what Dr. Ellis's reputation was as a teacher among the pupils. He paused before replying, and then, in substance, said as follows: "Dr. Ellis while unraveling any case was less brilliant than some other more fluent professors, and he was called a little 'slow,' and tedious as some thought. But upon our arrival at Vienna, by comparing our method of grappling with cases in the German hospitals with the desultory and imperfect examinations made by students of some noted schools in other large cities of our country, we soon found that we had been *more thoroughly drilled* than they. The result was that we understood more quickly and fully than they did all of the intricacies of a case."

No higher praise could be given to any professor than this simple, but significant, expression of one of his pupils.

He has left an unfinished work entitled, I believe, Symptomatology. On this he was laboring every hour that his disease permitted him to work, even to the the last few days of life. I sincerely hope that it has been so far finished that his literary executors can publish it. I was visiting him one morning while he sat half erect in bed. He was working then upon it, and was kind enough, at my request, to read to me a short extract. From that, I was led to feel that the work would not only add to his well-merited reputation, and serve the student and junior practitioner long after the writer's death; but that it would perhaps mark an era in the correct study and practice of clinical medicine similar to that which followed the publication of the great French teacher Louis's works. In truth, it seemed founded upon the same principle that underlies all of Louis's works, namely, the absolute necessity of making a most careful diagnosis of a case before proceeding to treat it. It was fortunate for several American students of fifty years ago, that even Louis, the great clinical teacher of that day, whose principles are now everywhere more or less perfectly carried into practice, was considered rather "slow" by his compatriots. Consequently our small "coterie" of Americans and of Swiss students had his oral instructions all to ourselves, which has, of course, been of immense advantage to every one of us during our lives.

In Dr. Ellis's connection with the Harvard School his influence was always for a higher education and better practical measures. He may be called a "conservative reformer." He never moved until his judgment approved of a plan. When once decided in his opinion, no obstruction could prevent him from boldly urging forward the cause against the opposition of even the most powerful. This was seen especially in his efforts at progress in the Medical School's late reforms. During his last illness, he told me that every step taken forward was violently and persistently opposed; and I sincerely believe that had it not been for the efficient work of Dr. Ellis, aided by his earnest *young* coadjutors in the Faculty, no reform would or could have been accomplished, and no one contributed more than our friend did as Dean of the Faculty to these very desirable results. During his long illness he, from love of the School, remained one of the Faculty. At length, his disease compelled him to resign his position of Dean, but he still hoped, even until the end, that in the intervals of his torture he would at times be able to meet, and to lecture to his pupils.

Surely I think that even with these brief hints at the various passages of the life, and allusions to the intellectual and moral qualities of our friend, we can feel, in the language of Wordsworth, that

> "The child is father to the man,"

and his days were

> "Bound each to each by natural piety."

May this fine example of a *life of true work* not be lost on any one of us.

Yours very truly, HENRY I. BOWDITCH.

DR. C. D. HOMANS said: Probably no one present knew Dr. Ellis so long or so intimately as I did. Perhaps Rev. Dr. Bartol may have done so, but certainly no one else. We were boys together, we were in college together, we were abroad together, and we have been together ever since. When in college Dr. Ellis though a good scholar was not brilliant, but was a hard student and a continuous worker. He was always a favorite, and was much interested in the pastimes of those days. He was an athlete, and was a member of the first boat club which was formed at Harvard College. We bought a boat together when we were in the Massachusetts General Hospital, and in our spare hours were fond of rowing on the Charles

River. The water then came up almost to the stone building which at that time comprised the entire hospital. He always kept up his love for athletic exercise, and even in his last years was very fond of walking, often preferring to go on foot rather than in his carriage to visit his patients. In some ways Dr. Ellis was particularly fortunate. He was hardly ever ill during his life until the commencement of the disease of which he died. He was fortunate also in possessing a competence, and was not obliged to trouble himself in regard to pecuniary matters. While a student in the Medical College he was one of the few who attracted the attention of the late Dr. J. B. S. Jackson, who for years made all the autopsies in and around Boston, and from him Dr. Ellis derived that love for, and knowledge of morbid anatomy which was so useful to him in after life. He was a worker as long as he lived. During his last illness, in fact up to within a few days of his death, he was engaged in the intervals of his sufferings in the preparation of a medical work for the press, which he left nearly finished.

It afforded him a great deal of satisfaction to be informed that, within a few days of his last attack, a letter had been received by a friend from a young physician, at present in Vienna, who stated that as a result of the careful clinical training received from Dr. Ellis, students from Boston were able to profit much more largely from the advantages offered by European hospitals than were those coming from other American cities and schools.

The disease from which Dr. Ellis died was ulcer of the duodenum. It first commenced about nine years ago, and continued to cause him more or less suffering from that time until his death. It was at first feared that it might be malignant, but the course of the disease disproved this, and it was then supposed to be ulcer of the stomach, but finally the diagnosis of duodenal ulcer was made, and was found by the autopsy to be correct. Death finally ensued from perforation and consequent peritonitis. Dr. Ellis never was willing to make a positive diagnosis of his own case. Through all his sickness he never lost his interest in what was going on. Just before his death he was planning what he would do when he got out again. For some time he was driven in a low carriage, and he was getting tired of this, and thought of buying a coupé as soon as he was strong enough to go out. During the last year he had been obliged to keep his bed much of the time, yet he always got out a little whenever possible. At times he would leave his bed and go for a drive, and and on returning would go at once to bed again. On the day of the last municipal election he rose, and was driven to the polls, and voted, and returning home went immediately to bed as usual, and never rose again. Through all his sickness and suffering he never murmured or complained, but was always patient and resigned, and when the pain became easier his cheerfulness and good humor at once returned. He was always glad to see his friends, and seldom spoke of his own distress.

In all he did Dr. Ellis was actuated by a strong sense of duty and intense love of his profession. He had the greatest interest in the University and Medical College, which he has proved by the fact that he has bequeathed his entire estate to the University after the death of his sister, most of it for the special benefit of the Medical School. As a physician he was loved and respected; as a counselor his advice was sought far and near; as a teacher and professor and public spirited man the entire community knew and appreciated his worth, while only those who were intimate with him can know how faithful he was to every demand which friendship might make upon him.

DR. SARGENT, of Worcester, having been requested, sent the following communication: —

"I am more than gratified, for I am also flattered, in being asked to contribute something to the testimonial of the general 'admiration of the noble and generous qualities' of Dr. Calvin Ellis, whose recent death is so great a loss to the profession and to the public.

"My acquaintance with Dr. Ellis was of long standing, but it was rather friendly than professional, for I never had occasion to have any professional relations with him whatever. It commenced in Paris in one of my periods of residence there, in the year 1850, and I see him now in his long walk from the neighborhood of the Garden of Plants to the schools and the hospitals. Then as always he was studious, sensible, thorough, faithful, and reliable. I renewed my acquaintance with him on his return to Boston, and was somewhat instrumental in his being placed on the commission for investigation of the peculiar pleuropneumonia of cattle, nearly twenty-five years ago. I had afterwards some other public relations with him. His sound sense always, his good judgment, and sincere convictions, and his fidelity to them, won, as they deserved, the greatest respect from the profession and the public.

"I never had the advantage of listening to any of his instructions from the professorial chair, but as I have had them described to me by young men who were so fortunate as to be his pupils, their thoroughness and richness and exactness must have been a very valuable contribution to the distinguished excellence which is so conspicuous in the Harvard Medical School.

"Commencing practice in Boston in a new era, when the microscope had just begun to peer into pathological anatomy, and its use was so seductive and engrossing as, perhaps, to warrant the witticism of our justly admired Dr. Holmes, then not more distinguished in literature than in medicine, and probably the best read American physician of that time, "Now for an era of little men," he recognized all that was true in what was new, and adopted all that was valuable. And so with him always. His scope was large, and great good sense directed his judgment and governed his work. His influence and his example have been a great good and an honor to the profession, and an advantage to the public.

"Let no man say that merit shall not command success."

The following letters were then read by the Secretary: —

HARVARD UNIVERSITY MEDICAL SCHOOL,
BOSTON, MASS., *January* 7, 1884.

DEAR SIR, — In reply to your letter of January 4th it gives me great pleasure to express to you the sympathy of the entire Medical Faculty in the feeling which has prompted your Society to appoint an evening for holding memorial exercises in honor of our late professor of clinical medicine, Dr. Calvin Ellis.

Although I am not authorized by the Faculty to promise any formal coöperation in your services, yet the individual members of that body will doubtless gladly avail themselves of the opportunity thus afforded

of testifying by their presence to their great respect for Dr. Ellis's noble character, and to their high appreciation of the value of his services as Dean of the Faculty during a most important epoch in the history of the School; as a clinical teacher of rare power and enthusiasm, and as a practitioner of medicine gifted with unusual soundness of judgment.

Yours very truly, H. P. Bowditch, *Dean.*

Dear Doctor, — I regret to say that owing to illness in my family I shall not be able to attend the meeting to-night.

Very truly yours, James C. White.

My dear Bowditch, — I am grieved not to be with you to night to show by my presence at least my appreciation of the character of our late associate and friend.

The profession will do justice to his memory.

Let me add my tribute to his fidelity as a physician, his ability as a lecturer, his integrity as a man.

Faithfully yours, D. Humphreys Storer.

Dr. Oliver Wendell Holmes, who was unable to be present, sent the following: —

CALVIN ELLIS.

My recollections of Dr. Ellis go back to the period of his pupilage. Of the large numbers of students with whom I have been in relation as teacher I do not remember one about whose future I felt more assured. He had all the signs of promise; active intelligence, industrious habits, love of his work, a vigorous frame, a cheerful temperament, an agreeable presence stamped with every outward sign of a sincere and manly character. I looked forward to his becoming a leading practitioner, with a confidence which his after career fully justified.

He united many rare qualifications. He had studied disease long and diligently, in the changes left by it in the various organs, and thus laid the foundations of his skill in diagnosis. But he never forgot that medical science is only the handle of the medical art. His assiduity, his patience, his self-devotion as a practitioner were unmeasured and unstinted, as I have known from personal observation. He forgot everything but his patient, he remembered everything for him in the chamber of sickness comforted by his quieting and commanding presence.

Every interest of the profession was very dear to him. The Medical Faculty of the University of which he was so long the Dean, found him a most willing laborer and a generous benefactor. The Boston Medical Library was indebted to him for valuable services and liberal contributions. He could not be otherwise than faithful in all that he undertook, for integrity — wholeness of character — belonged to him in its fullest measure.

Some of you knew this brother of ours more intimately than I can have known him. You will not think, I am confident, that I have exaggerated the excellences of this wise and skillful physician, this true and good man, whose loss will long be felt by the profession and the community. O. W. H.

New York, *January* 7, 1884.

My dear Sir, — I beg the privilege of offering to the members of your Society my sincere condolence in the loss which they have sustained. I had not the pleasure of a personal acquaintance with the late Calvin Ellis; but he was well known to me, and to all interested in medical education, as a painstaking, conscientious student of disease, and as an able, patient, and effective clinical teacher. In his death not only the School with which he was connected, and his professional brethren in your city, but the profession of the whole country and American medicine have sustained a great loss. Cut off in the midst of his useful labors and at an age when many more years of valuable services in behalf of medical education were to have been hoped for, our only consolation is in the reflection that he leaves a noble example which should incite others to follow in his footsteps.

Will you kindly remember me to those who will be present at the meeting on the 9th inst., with the assurance that I should have been glad to have been able to avail myself of your invitation to be present on that occasion.

With much esteem, very truly yours,

Austin Flint.

Rev. Dr. Bartol, upon being invited to make some remarks, spoke with great feeling and emotion as follows: I am here, Mr. Moderator, through courtesy and kindness on the part of this Society. I have listened with great interest and gratitude to what has been said by those who have spoken before me. The atmosphere of this meeting seems like a new consecration to duty. This Professor of Clinical Medicine whom we have assembled to honor to-night was not a *professor* in any other way. Whatever mistakes or vices the science of medicine or its sister professions of theology and law may be liable to, Dr. Ellis was free from them. There was in him no assumption of wisdom or authority. He took no bias in any unprofessional conduct.

In speaking of what Dr. Ellis was, and did, and said, we have referred to him in the *past*, but my feeling toward him is such that I can only speak of him in the *present* tense. Whatever hope we may have of some future life, or heaven after we have left the body, is revived by such fidelity. Every word which has been uttered to-night finds an echo in my own heart.

Dr. Edward Emerson, of Concord, rose and said: "I thank you for the opportunity to say a word for the older students. The character of Dr. Ellis as a physician has been dwelt on in an appropriate and worthy manner in the remarks of those who have spoken. One special feature of his life has, however, not been touched upon, and that is his position among those who were so fortunate as to be his pupils. He was a leader in the medical profession to a striking degree. He gave no long lectures on morals, delivered no tedious homilies, but his daily life exerted a gentle yet continuous influence, which was always a lesson to those about him, and was all the more powerfully felt because it was exerted unconsciously.

"As a friend Dr. Ellis was always thoughtful, unselfish, and devoted, as I know from my own experience. For some time I was in the habit of going to him for advice, not professional but personal, and he always took a most paternal interest in all which personally concerned those more closely associated with him."

The Secretary then read the following resolutions, which had been prepared by one of the members, and which were unanimously adopted: —

Resolved, The Section of Clinical Medicine of the Suffolk District Medical Society at its first meeting after the death of Dr. Calvin Ellis desires to express its admiration of him as a professional associate, a great clinical teacher, and above all as a man of noble character.

Resolved, That our respectful sympathies are hereby tendered to the sister of Dr. Ellis in this, her great loss.

Resolved, That the above resolutions, signed by the Chairman and Secretary of the Section, be forwarded to the sister of Dr. Ellis.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SURGICAL SECTION.

S. J. MIXTER, M. D., SECRETARY.

DECEMBER 5, 1883. DR. JOHN HOMANS reported

TWO CASES OF ABDOMINAL SECTION TO DISCOVER THE CAUSE OF INTESTINAL OBSTRUCTION.[1]

Dr. Homans showed the strictured intestine removed at the autopsy in the second case.

DR. J. C. WARREN said that he had had no experience in abdominal section, but had performed lumbar colotomy several times. In one case, that of a new-born infant with imperforate rectum, the incision was made in the right side, following the directions of M. Huguier, who shows that the descending colon lies near that side in very young children. The child recovered from the operation, but died some weeks afterwards, steady progressive emaciation following the operation. This form of emaciation, followed by death, has been noticed by some writers where an artificial anus has been made in the ascending colon. In acute cases of obstruction the treatment recommended by Mr. Jonathan Hutchinson, namely, profound anæsthesia, kneading of the abdomen, and inversion of the body, is often successful. Dr. Warren mentioned a case of obstruction in a new-born infant, of unknown cause, and not due to imperforate rectum. After etherization there was a spontaneous discharge of a large amount of meconium, followed by complete recovery.

DR. BUCKINGHAM had had no experience with ether in the acute cases referred to by Dr. Warren, but had had, within a few months, a case of probable intestinal obstruction in which full doses of opium failed to give more than temporary relief, but in which the persistent use of morphia on the fifth day, frequently repeated subcutaneously, and pushed to the limit of safety for twenty-four hours, was followed on the next day by passages of wind from the rectum, and three days later by several large dejections. He had previously reported a case successfully treated by opium.

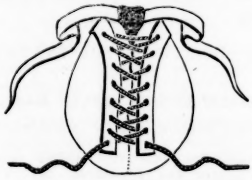
He inquired of the reader whether in operating for acute obstruction he would, in view of the difficulty in exact diagnosis and of the dangers from the escape of fæces into the abdominal cavity, expect to get as good a series of results as in ovariotomy.

DR. HOMANS replied that on account of the great distention of the intestines much more violent and prolonged handling of the abdominal contents was necessary in cases of obstruction than in an ordinary case of ovariotomy. Perhaps on this account it is better to open the first coil of intestine that presents itself. When a tumor has been for a long time growing in the abdominal cavity the recti and other muscles are relaxed, whereas in acute cases the muscles spring together, and it is very difficult to get a large enough opening in which to work. After operations of this nature it would seem that where the artificial opening is established in the upper part of the intestinal tract the danger of emaciation and starvation is greater than when the opening is near the rectum. Cases of artificial anus following abscess or strangulated hernia of the right side are, however, often seen where this condition has not been produced.

DR. GAY spoke of the discussion on this subject at the last meeting of the British Medical Association, where Mr. Lawson Tait recommended abdominal section in all cases of severe obstruction, while others regarded the groin or lumbar region as a better site for incision. Spencer Wells operates on the right side, as the bowel is more easily reached than on the left. Wounds of the peritonæum, under the present system of operating, are not attended with as great risk as was formerly supposed to be the case. Dr. Gay spoke of a case seen in consultation where complete obstruction had existed for two weeks. There was severe vomiting, but as no tumor could be felt in either the abdomen or pelvis, it was decided to await further developments before operating, and in a few days the bowels moved spontaneously. The patient recovered, and is now alive, at the end of eighteen months.

DR. CHADWICK spoke of the prolonged manipulation of the abdominal contents often found necessary in complicated cases of ovarian and other tumors, and which, generally, is followed by no bad results, mentioning, as example, a difficult Battey's operation in which the abdominal cavity was open for two hours with no consequent ill effects. Aspiration of the intestinal coils, to relieve distention during operation, seems to be a somewhat hazardous proceeding, as it is liable to be followed by peritonitis.

DR. MIXTER mentioned the not infrequent occurrence of a meso-colon as being an additional reason for preferring laparotomy to colotomy. Whenever this condition exists, and it is impossible to diagnosticate its presence or absence before operation, the peritoneal cavity is necessarily opened, and under these circumstances the operation and after-treatment are much more simple when the wound is in the anterior abdominal wall. He had recently seen in the dissecting room a subject in which a broad meso-colon was present.



DR. CHEEVER said that much more successful results could be looked for in cases of chronic obstruction than in cases of acute obstipation, especially in children, where the symptoms are very rapid, and valuable time is wasted in vain medication, and operative interference comes too late. In intussusception the intestine soon becomes adherent and perhaps gangrenous. In such cases everything depends on an early operation. A boy, seen by Dr. Cheever in consultation, had had complete obstipation for some days. The abdomen was opened, and a constricting band was found and divided. Immediately there was an immense discharge of gas and fæces. Unfortunately, acute peritonitis was already present, and the patient died the next day. Probably his life could have been saved by an earlier operation. Dr. Cheever had never seen peritonitis following aspiration. Even stabs of the abdomen, with protrusion of intestines and omentum, as often seen in hospital practice, almost always recov-

[1] See page 145 of this number of the JOURNAL.

er, as, for instance, the case of a child brought to the City Hospital with a coil of intestine lying on the outside of the abdomen, having probably been exposed for ten or twelve hours. The opening was enlarged, and the bowel returned, after being thoroughly washed and warmed. Recovery followed without a bad symptom. As bearing on the subject of starvation following openings of the upper part of the intestinal tract, Dr. Cheever spoke of a case of artificial anus, caused by pelvic abscess, and followed by progressive emaciation and death.

A SUBSTITUTE FOR STRAPPING THE TESTICLE AND THE TREATMENT OF HYDROCELE.

Dr. J. C. Warren showed a chamois-leather bag which he had devised for the purpose of exerting pressure on a small collection of fluid left in the tunica vaginalis remaining after an operation for radical cure. The bag can easily be applied by isolating that portion of the scrotum containing the testicle to be compressed and forming a pedicle, which is preserved by tightening the chamois-leather string. The bag is then laced from above downwards, and, if it has been made to fit snugly, exercises a gentle and equable pressure. If it is

necessary to increase the pressure a few turns of a common narrow roller bandage around the equator of the globular mass are all that is necessary. This bag is free from the well-known discomforts of plaster, is easily made and applied, and can be removed and reapplied by the patient himself as often as is desirable, thus avoiding excoriation at constricting points. In the single case in which it was used the effusion promptly disappeared, and has not since returned at an interval of nine months.

Dr. Warren spoke of the advantages of Dr. Levis's method of treating hydrocele by the injection of one drachm of the liquefied crystals of carbolic acid. It appears to be specially adapted to the lighter forms of the disease, is almost painless, and produces very moderate reaction, so that the private patients he had operated upon on a Saturday were able to be about again on the following Monday. In but one case had he found any perceptible discoloration of the urine, although this symptom of carbolic absorption had been carefully looked for in all his cases. He recommended the substitution of the ordinary horse subcutaneous syringe, with a trocar attachment to one of the needles, instead of the ordinary trocar and Sims' ear syringe which Dr. Levis uses. In large hydroceles of long standing the acid does not produce any perceptible effect upon the disease. He spoke of the discomforts and comparatively long confinement attending the operation by incision, even under the most careful antiseptic precautions, as laid down by Volkmann. The constitutional disturbance and the local œdema, with occasionally sloughing of the connective tissue, even when the wound has been kept aseptic, make this an operation which should be reserved for those cases only which are not amenable to other modes of treatment.

Dr. Strong spoke of the difficulty of keeping a Lister dressing on the scrotum after operation. There is always less danger of œdema when the scrotum is kept raised.

Dr. Gavin, in injecting hydroceles, uses Delano's rubber bulb syringe, as being more convenient than the cylinder syringe.

Dr. Marcy had had abscess and sloughing follow the injection of a drachm of liquefied carbolic acid crystals. One half that amount has been found to be equally effectual in curing the hydrocele, and is not accompanied by so great danger of excessive inflammation.

Dr. Cheever never attempts a radical cure in old men, but advises them to be content with tappings repeated as often as necessary, as a low form of inflammatory œdema of the scrotum, ending in death, is described as peculiar to the aged.

FOREIGN BODIES REMOVED FROM THE ŒSOPHAGUS AND THE URETHRA.

Dr. Gay showed a large fragment of turkey bone removed the night before, by a bristle probang, from the œsophagus of an old lady; and also showed a black-headed steel bonnet pin, six inches long, removed from the urethra of a man seventy-five years old, who, "having nothing else to do," had introduced it head first, and had let it slip through his fingers.

MASSACHUSETTS MEDICAL SOCIETY.

COUNCILORS' MEETING.

A stated meeting of the Councilors was held at the Medical Library, Boston, on Wednesday, 6th inst.

The meeting was called to order at eleven A. M., by the President, Dr. Alfred Hosmer. Eighty-six Councilors indicated their presence by signing the roll.

APPOINTMENT OF DELEGATES AND COMMITTEES.

On nomination by the Chair the following delegates to other State Medical Societies were appointed: —

Maine: Drs. F. A. Howe, of Newburyport; J. T. G. Nichols, of Cambridge.

New Hampshire: Drs. G. M. Morse, of Clinton; G. W. Snow, of Newburyport.

Rhode Island: Drs. J. Dwelly, of Fall River; C. Howe, of Taunton.

Connecticut: Drs. G. W. Burdett, of Clinton; E. C. Richardson, of Ware.

New Jersey: Drs. H. M. Holmes, of Adams; S. W. Bowles, of Springfield.

Committees were appointed: —

To Audit the Treasurer's Accounts: Drs. C. C. Tower, J. O. Marble.

To Examine the Library: Drs. O. W. Doe, Z. B. Adams.

To Examine the By-Laws of District Societies: Drs. S. D. Presbrey, J. C. White, F. W. Chapin.

REPORT OF COMMITTEE ON DIPLOMAS.

Dr. W. L. Richardson, for the Committee on Medical Diplomas, presented the following: —

The Committee on Diplomas, to whom was referred the petition of the College of Physicians and Surgeons, of Boston, requesting to be placed on the list of colleges whose diplomas are recognized by the Massachusetts Medical Society, beg leave to submit the following Report: —

The Committee have devoted a great deal of time in ascertaining the facts on which their report is based. Much of the evidence which they obtained was of a confidential character and such as could not therefore properly be made public.

They have carefully considered the circumstances which led to the establishment of the college; the character and professional ability of the gentlemen who have, at one time or another, formed its corps of instructors; the facilities at the disposal of these teachers for giving clinical as well as didactic teaching; the requirements for a degree and the manner in which those requirements have been enforced; the nature of the examinations, and the character of the candidates at the time they were admitted to receive their degree. In accordance with instructions received from the Councilors, they have given the petitioners a hearing, at which the dean, registrar, and two other members of the Faculty were present. Subsequently the committee, in company with the gentlemen above mentioned, visited the rooms occupied by the college and inspected the facilities there shown for the didactic and clinical teaching of the students.

As the result of their investigation the committee were impressed with the fact that, while the origin of the School was, to say the least, questionable, yet certain members of the present Faculty were evidently endeavoring to so manage it as to furnish a fair medical education to such students as were unable to pay the fees charged by the best known schools in the country, and to give the degree of M. D. under such restrictions as would enforce the requirements contained in their annual announcements. The committee was also of the opinion that such has not always been the practice in this School.

Carefully weighing all the facts in their possession, the committee would report that they are unwilling to advise that the degree of M. D., heretofore given by this School, be recognized, and also, considering the effort now apparently being made by certain members of the Faculty to improve the character of the college, they are unwilling to pass judgment on its probable future.

They would, therefore, recommend that at the present time the petitioners have leave to withdraw.

WILLIAM L. RICHARDSON.
A. H. COWDREY.
EDWARD J. FORSTER.

BOSTON, *February* 1, 1884.

DR. DUDLEY said he was confident the committee had been misled to some extent in their investigation, though he doubted not they had performed their duty thoroughly. He moved that the subject be recommitted to the committee so far as the future male graduates of the college are concerned.

DR. RICHARDSON asked if the mover expected a report at the next meeting? It would be useless to recommit the matter if a report is to be made in the near future. He said this with no intention to "pigeon hole" the question if no time was fixed for the committee's report.

DR. DUDLEY replied that he would not press the matter as to the time of the report.

The motion was then adopted.

Voted, on motion of DR. DUDLEY, that the committee be instructed to give the college a hearing before making another report.

ROOMS.

The treasurer, DR. DRAPER, called attention to the fact that the lease of rooms from the Medical Library Association will expire at the end of the present month.

DR. MILLET expressed the hope that a better place would be provided for the future meetings of the Council.

Voted, That the matter be referred to the officers of the Society with full powers.

AMENDMENT TO THE BY-LAWS.

DR. WINSOR offered the following: —

After the words "in writing," in the second line of the first paragraph of By-Law XXXIII., insert the words, "and may originate either in the Society or its Council."

A discussion ensued, followed by the rejection of the amendment — ten in the affirmative, forty in the negative.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

SEVENTY-EIGHTH ANNUAL MEETING.

FIRST DAY, FEBRUARY 5TH. MORNING SESSION.

THE Society convened in Geological Hall, Albany, and after prayer the President, DR. ALEXANDER HUTCHINS, of Brooklyn, read his inaugural address. Various committees were then appointed, after which communications were received from New York, Albany, Ontario, and Washington County Medical Societies.

DR. W. M. CARPENTER read a memoir of the late Dr. J. Marion Sims.

RESOLUTIONS, ETC.

DR. A. JACOBI offered a resolution, which was unanimously adopted, urging that Congress should provide a fire-proof building for the Museum and Library of the Surgeon-General's Office, and calling for the prompt publication of the remainder of the Catalogue, and the further increase of the Library.

DR. S. O. VANDERPOEL called the attention of the members to the effort to raise a fund for the erection of a suitable memorial of the late Dr. J. Marion Sims in the city of New York, and commended the project to their favorable consideration.

DR. T. F. ROCHESTER, of Buffalo, from the Committee on Prize Essays, reported in favor of awarding the Merritt H. Cash prize to Dr. Ghislani Durant, of New York, for his essay on Tubercles of the Breast, and commending an essay on Consumption, author unknown, as worthy of publication.

The following papers were then read and discussed to some extent: Two Unusual Cases in Obstetrical Practice, by Dr. W. C. Wey, of Elmira; A Case of Double Harelip, by Dr. J. P. Creveling, of Auburn; Prophylaxis of Summer Complaint in Children, by Dr. D. Little, of Rochester; Canalization as applied to Amputation of the Female Breast to assure Primary

Union under One Dressing, by Dr. A. G. Gerster, of New York; An Operation for correcting Deformity of the Auricle, by Dr. O. D. Pomeroy, of New York; and Poisoning by Potassium Chlorate, by Dr. George B. Fowler, of New York.

AFTERNOON SESSION.

The following papers were presented: The Establishment of Hospitals in Small Cities, by Dr. E. H. Parker, of Poughkeepsie; Congenital Lipoma, by Dr. A. Jacobi, of New York; The Value of Electricity in Diagnosis, by Dr. L. E. Felton, of Potsdam; A New Method of Partial Extirpation of the Cancerous Uterus, by Dr. E. Van de Warker, of Syracuse; Orbital Cellulitis, by Dr. T. R. Pooley, of New York; Operations for the Closure of the Hard and Soft Palate, with Results, by Dr. A. Vanderveer, of Albany; A Case of Sympathetic Serous Iritis, with Remarks, by Dr. David Webster, of New York; A Plea for the Pharmacopœia, by Dr. Laurence Johnson, of New York; and Horse-Hair Sutures, by Dr. Daniel Lewis, of New York.

The report of the Committee on Experimental Medicine was also read by Dr. J. G. Curtis, of New York, its secretary.

EVENING SESSION.

This session was devoted to the subject of

THE CODE OF ETHICS.

On motion of Dr. Hodge the communication of the Ontario County Society, which had been laid upon the table at the morning session, was taken up. It affirmed the allegiance of the Society to the National Code of Ethics, and directed its delegates to endeavor to secure the return of the State Society to the same.

On motion of Dr. Piffard it was ordered placed on file.

Dr. Baker presented a communication from the Niagara County Society protesting against the action of the State Society in adopting the New Code.

In the absence of Dr. Didama, Dr. Moore, of Rochester, moved that the resolution of the former, which had been laid upon the table last year, should be taken up and read. Carried. This provided for the repeal of the action of the Society in 1882, and left the National Code in force.

Dr. Rochester, of Buffalo, in moving the adoption of the resolution, remarked that he believed that such action would result in restoring unity and good feeling, and that it was the duty of the members to consider first the best interests of the profession, and afterwards those of the Society. This was now in rebellion to the American Medical Association, to which it ought to have appealed before adopting the New Code of Ethics.

Dr. Didama having entered made some extended remarks in advocacy of his resolution. Forty out of sixty county societies in the State, he said, disapproved of the action of the State Society, and the adherents of the New Code numbered less than one fifth of the regular profession in the State. He called, therefore, on the minority to give up their Code, and refer the matter to the American Medical Association for arbitration.

After remarks by Drs. Roosa and Moore the ayes and nays were called for on Dr. Didama's resolution, when it was found to be lost by a vote of 107 to 124.

A motion by Dr. Jacobi to abolish all codes was discussed, and finally withdrawn, after which the Society adjourned.

SECOND DAY, FEBRUARY 6TH. MORNING SESSION.

THE LICENSING OF MEDICAL PRACTITIONERS.

Reports from the treasurer and a number of committees having been received, the recommendation of the Committee on Legislation that the bill known as Assembly Bill No. 120 should receive the sanction of the Society, and that the committee should be authorized to urge its passage, was made the special order of the day. This bill provides that on or before the first day of June next the Governor shall appoint a medical faculty of the "University of the State of New York," to consist of nine members (six regulars, two homœopaths, and one eclectic), three of whom shall serve for three years, three for four years, and three for five years, whose duty it shall be to examine all applicants for license to practice medicine and surgery, to confer the degree of M. D., and to refuse or revoke licenses.

A motion by Dr. Hopkins, of Buffalo, to adopt the report, was discussed by Drs. Loomis, Piffard, Jacobi and Hopkins, and Dr. Agnew then offered as an amendment that the report be returned to the committee with instructions to draft and advocate the passage of a bill to regulate the licensing of medical practitioners in the State, and that four additional members be added to the committee for that purpose. After further discussion the amendment was laid on the table.

AFTERNOON SESSION.

The discussion of the same subject was continued, and Dr. Joseph W. Howe, of New York, offered an amendment to the effect in lieu of all proposed legislation on the subject of granting licenses, a committee of the State Society should be appointed to draft a plan for a commission to visit the medical colleges, superintend and inspect their methods of examination, and report to the Society at its annual meetings. After a lengthy debate, in which Drs. Dalton, Hopkins, Vanderpoel, Jacobi, Seymour, Roosa, Loomis, Wey, Rochester, Perkins, Baker, Campbell, Sturgis, Frazer, and Vanderpoel participated, it was finally resolved, on motion of Dr. Piffard, that the question should be referred to Drs. A. L. Loomis, A. Vanderveer, and J. G. Curtis, in conjunction with the Committee on Legislation, who should report to the Society next year a bill covering the subject under discussion.

The President announced as a committee to coöperate with the Society for the Prevention of Cruelty to Children, Drs. Jacobi, Vanderpoel, and Moore.

PRIZE ESSAYS.

Dr. Rochester, from the Committee on Prize Essays, announced that the committee wished to modify their report made at a previous session.

The minority report was then read by Dr. W. W. Potter, of Buffalo, and in this it was stated that the Merritt H. Cash prize was designed for an original essay, and that the essay on Tubercles of the Breast, which was fifty pages in length, contained but thirteen of original matter.

On motion of Dr. Vanderpoel the report was adopted, and no award of the prize was made.

The following papers were read: Foerster's Method of Ripening Cataract, by Dr. Mittendorf, of New York; House Sanitation, as it is, and as it should be, by Dr. Sheehan, of Rochester; Spontaneous Pyemia, by Dr. Todd, of Parish; the Care and Preservation of Medical

Pamphlets, by Dr. Fisher, of Sing Sing; Strangulated Hernia, by Dr. Chapman, of Medina; Note on the Treatment of the Derangements of the Digestive Organs, by Dr. Castle, of New York; Hay Fever, by Dr. Roe, of Rochester; Dysmenorrhœa and its Treatment by Dilatation, by Dr. Potter, of Buffalo; Primary Drainage and Secondary Drainage, by Dr. Fowler, of Brooklyn; the Mechanical Treatment of Hip-Joint Disease, by Dr. M. J. Roberts, of New York; Synovitis of the Knee and Ankle Joints, by Dr. Phelps, of Chateaugay; and Morbid Somnolence, by Dr. Dana, of New York.

EVENING SESSION.

The annual address was delivered by the President, DR. HUTCHINS, in the assembly chamber, on the subject,

THE RECIPROCAL ATTITUDE OF THE MEDICAL PROFESSION AND THE COMMUNITY.

In it he advocated the choice by the community, through its law-makers, of an acceptable judicious body to decide as to the fitness of all candidates to assume the responsibilities of the profession. At the close of the address the Society and its invited guests adjourned to the Delavan House, where the annual banquet was held, and the usual toasts responded to.

THIRD DAY, FEBRUARY 7TH. MORNING SESSION.

DR. PARTRIDGE, of New York, read a paper on Face Presentations, and DR. JACOBI, of New York, one on Arsenic and Digitalis in Phthisis.

ELECTION OF OFFICERS.

The report of the Nominating Committee was then made, and the following officers were elected for the ensuing year: President, Dr. B. F. Sherman, of Ogdensburg; Vice-President, Dr. P. R. H. Sawyer, of Bedford; Secretary, Dr. William M. Smith, of Syracuse; Treasurer, Dr. Charles H. Porter, of Albany; Censors, Southern District, Drs. F. A. Castle, G. H. Fox, David Webster; Eastern District, Drs. E. D. Ferguson, N. L. Snow, Le Roy McLean; Middle District, Drs. A. Churchill, J. K. Chamberlyne, Robert Frazier; Western District, Drs. T. F. Rochester, R. L. Hovey, T. Deman. The various committees were also elected, as well as a number of permanent members and the delegates to different State Medical Societies, the Canadian Medical Association, the British Medical Association, and the Ontario Medical Association. Drs. Vanderpoel, Phelps, Roe, Vanderveer, Creveling, Bailey, Hutchins, Jacobi, and Shrady were elected delegates to the International Medical Congress at Copenhagen, and Dr. W. G. Bronson, of Connecticut, was elected an honorary member of the Society. After the usual votes of thanks the Society then adjourned.

Recent Literature.

The Principles and Practice of Surgery. Vol. III. By D. HAYES AGNEW, M. D., LL. D. J. B. Lippincott & Co. Philadelphia: 1883.

This volume completes the System of Surgery upon which Dr. Agnew has been at work for the past five years.

It contains chapters upon Diseases of the Eye, the Ear, and other branches in which the general surgeon is being rapidly displaced by the specialist, and the thoroughness with which these subjects are treated shows the training of the old school, before medical practice underwent its modern subdivisions.

The comprehensiveness of this work will make it of especial value to the practitioner at a distance from cities and hospitals, who is thrown upon his own resources; and the suggestions for treatment are conservative and wise.

The chapters upon Syphilis and Tumors are carefully and concisely written, presenting their subjects in so condensed a form that a vast amount of information is given in a very small space. The illustrations of the tumors are particularly good.

When so much ground is covered, and the space is so limited, an accurate account of all surgical procedures is not of course possible; still, the chapter on Orthopædic Surgery is hardly complete with no account of osteoclasis, as applied either to bow legs or to cases of hip anchylosis with faulty position.

MacEwen's operation for knock-knee is figured as if a wedge-shaped piece of bone were removed from the femur, whereas the operation really consists in a simple section of the bone with a chisel.

As a guide to practice, Agnew's Surgery will take a high place, not upon the book-shelves, but in the estimation of practitioners. If, however, a complete investigation of a special subject is desired, it will not be found to compare with several of the modern encyclopædic works.

The Fourth Annual Report of the State Board of Health of South Carolina.

This report appears somewhat diminished in its material contents, with the following apology as an introduction: "Heretofore much space has been given to papers upon sanitary matters and preventive medicine; . . . but objections having arisen from those whose opinions are entitled to respect, to this mode of circulating what cannot but be deemed valuable information, and which is very generally adopted by the Boards of Health of other States, the Executive Committee has decided, in deference to the views of those who urge the objection, and who would have the report wear less 'the appearance of a medical journal,' to publish this year only such papers as have been supplied by the members of the committee, and by the county and town Boards of Health."

The Report contains the following papers: —

Report of the Secretary, with Details of the Quarterly Meetings of the Board.

Reports of Sub-Boards, each of which has Supervision of a County.

Report of Committee on the Medical Topography of South Carolina, containing Valuable Information as to the Climatic and Physical Features of Different Sections of the State, by Dr. F. F. Gary.

Brief Reports on Endemic and Epidemic Diseases, and also on Penal and Charitable Institutions, by Dr. J. F. Prioleau.

Report on Quarantine, by Dr. T. G. Simons.

On the Sanitary Regulation of Schools, by Dr. C. R. Taber.

— "The premature Brougham" is the suggestive expression by which a correspondent of an English journal refers to a common burden which weighs down the young practitioner.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 14, 1884.

TRANSITORY APHASIA IN TYPHOID FEVER.

EVERY clinical observer who may have had occasion to see a large number of cases is well aware of the numerous and varied complications attendant upon typhoid fever, complications arising largely from the changed state of the blood and tissues. Derangements of the mental faculties due to cerebral anæmia and functional torpor of the gray matter are sufficiently common to be the rule rather than the exception, but a genuine transitory aphasia attendant upon typhoid is very rare.

A case of this sort occurring in Professor Bäumler's clinic at Freiburg gave rise to an investigation of the literature of typhoid fever and the collection of twenty-seven other cases, the details of which in connection with nine more cases complicating other acute exanthemata — five in variola, two in measles, one in scarlet fever — and erysipelas is not devoid of interest.[1]

The disturbances of speech in these cases belonged to the amnesic or ataxic aphasias, or exhibited a mixture of the two classes, and a very large proportion, twenty-five out of twenty-eight of them, occurred in children, as might be anticipated from the greater impressionability of the nervous system in children. The majority, eighteen, of the patients were between seven and thirteen years of age, five were between three and six years, one was fourteen, and the age of one child was not fixed. Only ten of the cases were females.

When grouped according to the period at which the aphasia declared itself we find twenty cases developing during the course of the fever, and six during the stage of convalescence, the second and third weeks having been the period of election. In only one case is any paralysis reported, and that a right hemiplegia, in a boy, developing fourteen days after the appearance of the aphasia, and disappearing entirely in a short time, although in three other children a transitory paresis or incoördination of movements of the upper or lower extremities was manifested. In two cases deafness, a not very uncommon complication in adults, without aphasia, was observed.

In most of the cases the typhoid fever was of a severe type, as shown by other nervous symptoms; consciousness, however, was not lost in any, or, at the most, only dimmed for a short time. Only one case ended fatally, the others recovering entirely. In most of these patients the disturbance of speech lasted from three to six weeks, the shortest duration being two days, and the two longest four months and four years respectively. In general the power of speech returned almost as suddenly as it was lost, with the exception of some little hesitation at the beginning in finding the proper expression.

Of the cases of transitory aphasia reported as attendant upon the acute exanthemata, one, in variola, occurred during the prodromal stage; one, in scarlet fever, at the height of the disease; four, of which three accompanied variola and one measles, toward the end of the febrile stage; and two, one in measles and one in erysipelas, during convalescence. All of these cases, except two of small-pox, also ended in recovery. In proportion to the relative frequency of the diseases, aphasia would seem from this to be a less uncommon complication of variola than of typhoid.

Beyond a somewhat severe type of disease and more or less hyperpyrexia these cases exhibit no especial ætiological factor in common to account for the occurrence of the aphasia, and in the two cases followed by autopsies, one of typhoid and one of small-pox, with the exception of a moderate degree of œdema no macroscopic changes were detected in the brain.

ANOTHER UNITED STATES PHARMACOPŒIA. IS IT NEEDED?

THE bill introduced into Congress last month by Mr. Randall, of Pennsylvania, providing for a national pharmacopœia, to be prepared under the auspices of army, navy, and marine hospital surgeons, seems, at first sight, one which ought to be favored by the medical and pharmaceutical professions throughout the country.

We suspect, however, that a certain proportion of the enthusiasm which such a proposition may awake would be due to ignorance of the position now held by the United States Pharmacopœia, which, although in no sense emanating from the government, has been adopted as a legal standard of strength and purity in several States, and by the Treasury Department of the United States, as shown by the following extract from the Customs Regulations, 1874: "Art. 450. All imported drugs, medicines, and medicinal preparations are to be tested in reference to strength and purity by the standard established by the United States, Edinburgh, London, French, and German Pharmacopœias and Dispensatories. If the articles . . . prove to conform in strength and purity to the pharmacopœia and dispensatory of the country of their origin they are exempt from the penalties of the law, but if produced, manufactured, or prepared in any other country than the last mentioned, they must conform to the United States Pharmacopœia and Dispensatory." The Dispensatory is mentioned in the preceding regulation because the United States Pharmacopœia of 1870 was very meagre in its details, and the Dispensatory alone gave much of that which is now, by the new revision of 1880, contained in the last Pharmacopœia. This Pharmacopœia has been compiled, arranged, and stud-

ied by delegates from all parts of the Union, and embodies special suggestions from many medical societies and specially skilled individuals.

It must certainly be considered to fairly represent the wishes and opinions of all portions of the United States as fully as the one proposed is likely to do.

The result has been one of which we have no reason to be ashamed. The United States Pharmacopœia is admitted by competent authorities to be one of the best national pharmacopœias, if not the best, in the world, and, what is very much to the purpose, arrangements were made by the convention which framed it for maintaining it in its present high position and keeping it abreast of the progress of science. We cannot see what is to be gained by another. If the new one is worse than the old it certainly is not wanted. If it is equally as good we shall have the intolerable nuisance of two authorities, unless the government can compulsorily retire the present work, not on account of age or inefficiency, but on the lowest political ground of making room for somebody who wants the place and has a "claim."

The chances of a new pharmacopœia being distinctly better in the sense of being more scientific, more convenient, or more fully representing the wishes of the country as regards the selection of articles to fill its lists, cannot be considered very good when we remember that the gentlemen chosen from the three government corps (which corps, by the way, were fully represented in the last convention for revision) can hardly be considered experts, if, indeed, they be not almost amateurs, and the work must be largely done either by the men who have already given their best to the present Pharmacopœia, or by others not at all likely to be their superiors in knowledge, zeal, or experience; and, if current reports relative to the influences brought to bear upon the selection of officers for duty are true, the fear that political and social considerations may have more weight than scientific and professional ones is by no means an unfounded one.

If the United States want a more authoritative pharmacopœia they can easily give the existing one all the authority desired. May we be pardoned the surmise that disappointment at the control of the present Pharmacopœia being no longer almost exclusively vested in the "great medical centre" has something to do with this new move!

MEDICAL ATTENDANCE UPON SICK JURORS.

A RECENT decision of the Massachusetts Supreme Court concerning the attendance of a physician upon a sick juror has some interest. The defendant in a trial by jury, against whom a verdict was rendered, appealed to have it set aside, and a new trial granted on account of the acts of the officer having the jury in charge. It seems that the court was adjourned Friday afternoon until Monday morning, leaving the jury in charge of an officer, with instructions to discharge them if they did not agree by ten o'clock P. M. that evening, and if they agreed to have them seal up the verdict and return it to court on Monday morning. After the judge had left town the foreman of the jury told the officer that a juror was sick, had a chill, and required some brandy. The officer saw the juror, and thought him sick. He sent to a druggist and got a two-ounce vial of brandy, and passed it to the foreman. Afterwards another juror fell upon the floor in a fit, and the officer sent for a physician, and allowed him to administer to the juror in the fit, who recovered. Subsequently the jury agreed upon a verdict for the plaintiff, sealed it up, and were discharged, and returned the verdict to the court on Monday. The presiding judge in superior court was satisfied that the officer acted in entire good faith, and the defendant was in no way prejudiced by his acts.

Upon the motion for a new trial the court said: "We do not think that the rules of law imperatively require us to hold that it is a legal cause for us to set aside the verdict when a juror, who is seized with a sudden temporary indisposition, without the intervention or knowledge of either party to the suit, obtains and uses, merely for the relief of his disease or pain, a small quantity of spirits, and where it appears that he is not thereby disqualified for the due performance of his duty as a juror.

"The question of the effect of the introduction of the physician into the jury-room for the purpose of giving medical aid or relief to the juror who appears to have stood in pressing need thereof is not free from difficulty. It is, however, obvious that a merely temporary attack of sickness, though it may for the time being incapacitate the juror, is not a necessary ground for the discharge of the jury. It is proper, when the circumstances will admit, to await the result, and see if, within a reasonable time, he so far recovers as to enable the trial to proceed or a verdict to be returned. If such a sickness is brought to the attention of the court while the jury is deliberating on their verdict, and medical attendance appears to be necessary, the better way ordinarily would seem to be for the court to select a suitable physician, and to caution him in advance not to enter into any conversation with any of the jury upon the case, or upon any matter except such as may be directly connected with the needed relief for the disorder. In the present case the judge was not accessible at the time, but nothing appears to have been done differently from what might well have been ordered by him. There is no reason to suppose that either the officer or physician said anything to any juror which in any way bore upon the case, or that the course of substantial justice was to any extent perverted or disturbed by what occurred. This was a matter which was especially for the presiding justice to investigate. We cannot say, as a matter of law, that a new trial must necessarily be granted."

MEDICAL NOTES.

— A correspondent of *Science* reports a remarkable instance of protraction of life in a spider during complete deprivation of food. He says that on the

15th day of October, 1881, he inclosed a spider in a small paper box. From that day to the 7th day of May, 1882 (two hundred and four days), he carefully watched and daily inspected the prisoner, and can positively affirm that he partook of no food or water. The box in which the spider was confined was as clean and white as white paper could make it, and remained so while he continued to occupy it, except for the appearance of a few dark specks, which were supposed to be the droppings of the prisoner. He was carefully observed every day, and sometimes two or three times in a day, and no emaciation or symptoms of weakness, or even irritability of temper, were detected while he lived. He always appeared as active, and looked as plump and healthy, as he did the day he was dropped into the box, until within three days of his death, when it was first observed that when the box was tipped he would fall from his position.

NEW YORK.

— In consequence of the action of the State Medical Society in resolving to adhere to the New Code of Ethics, a number of members who are supporters of the National Code met at the Delavan House, Albany, February 6th, and formed a new State society, which is to be known as the New York State Medical Association. Sixty-five gentlemen from all parts of the State signed the roll, and much enthusiasm was displayed. The following officers were elected: President, Dr. H. D. Didama, of Onondaga County; Vice-Presidents, First District, Dr. J. Mortimer Craw, Jefferson County; Second District, Dr. Tabor B. Reynolds, Saratoga County; Fourth District, Dr. B. L. Hovey, Monroe County; Fifth District, Dr. N. C. Husted, Westchester County; Recording Secretary, Dr. Caleb Green, Cortland County; Corresponding Secretary, Dr. E. D. Ferguson, Rensselaer County; Treasurer, Dr. John H. Hinton, New York County; Advisory Council, Drs. John P. Gray, Conant Sawyer, J. W. Moore, Thomas Wilson, Ely Van de Warker, Frederick Hyde, M. W. Townsend, E. M. Moore, E. R. Squibb, Austin Flint, Jr., and J. W. S. Greeley. The Association will next meet in New York on the third Tuesday in November, 1884.

— The New York State Veterinary Association met at Cooper Institute, New York, on the 6th of February, and completed its organization by electing the following officers: President, Dr. Robert R. W. Finlay; Vice-President, Dr. L. V. Plageman; Secretary, Dr. Halloway; Treasurer, Dr. Middletown, of Fishkill. The object of the Society is the elevation of veterinary science, and its membership is now about sixty.

— The act prohibiting the manufacture of cigars in tenement houses (except on the ground floor), which went into force in October last, has been decided by the Court of Appeals to be unconstitutional. In the case in which its constitutionality was tested, it was claimed by counsel that on the face of the bill it was shown that the business was not considered by the Legislature to be detrimental to public health, because the law allowed it to be carried on upon the ground floor, and what was unhealthful up-stairs could not certainly be less so on the lower floor. In addition to the claim that the law was unconstitutional, it was urged that the making of cigars in tenement houses was not detrimental to the health even of those engaged in the business, and a resolution passed by the Board of Health in January, 1883, while the bill was before the Assembly, was presented, which stated that "it is the opinion of this board that the health of the tenement population is not jeopardized by the manufacture of cigars in such houses."

— At a meeting of the New York Anthropological Society, held February 6th, the subject of mesmerism was discussed, and Dr. Jarvis related a case in which he had successfully employed it as a means for producing anæsthesia while he performed a difficult and painful operation upon the subject.

— In his annual message Mayor Edson says, in regard to the new Croton Aqueduct, that it is a source of gratification and encouragement to the Commissioners that up to this time the modified route determined upon has met with very slight opposition or objection from property owners or others, and that as soon as the surveys are completed, and the requirements of the law can be fulfilled, the commissioners will take possession of the required lands and begin the work. He thinks this will be done early in the spring, and that the aqueduct will be completed within thirty months from the date of the commencement of construction. He praises the health department for its energy and efficiency, and expresses the opinion that the remarkable healthfulness of the city during the past year is in a great degree due to the constant watchfulness of the department and to the vigorous enforcement by its officers of the sanitary laws. The number of deaths occurring in the city during the year was 33,958, a decrease of 3966 as compared with the previous year. The death-rate, in comparison with that of other large cities, he thinks is not excessive, particularly when the special circumstances existing in New York are taken into consideration, namely, the absolute completeness of the records of deaths; the large tenement-house population, due to the insular position of the city; the great foreign immigration to this part, where many aged, weak, and sickly immigrants remain to die; the influx of sick and poor from the surrounding country and from interior cities, who seek the benefits of the treatment to be obtained in the hospitals; and the great number of visitors and temporary residents always in the city for medical treatment — all contributing to swell the mortality and increase the apparent death-rate.

The mayor calls attention to the notable decrease in the number of deaths from zymotic diseases, — the number from small-pox in 1883 being twelve, against 259 in 1882; from scarlatina, 745, against 2066 in 1882; and from diphtheria, 1010, against 1525 in 1882, — and then proceeds to give a synopsis of the work performed during the year by the Board of Health in its various departments.

— The eleventh annual Commencement of the Training School for Nurses attached to Bellevue Hos-

pital was held on the 8th of January, when twenty-seven graduates received diplomas, and Prof. T. Gaillard Thomas made an address to the class, from which the following extract is taken: "The lady managers of this school have looked for and found in it a field which lay fallow at their very door, and yet a field as noble, as useful, and as consonant with woman's nature as any that civilization offers to mankind. The educated nurse is the lieutenant of the physician in the sick room, one who replaces him in his absence, watches for him the approach of danger, reports for him the progress of the case, and in time of sudden and dangerous emergencies acts for him to the best of her ability. Yet we ask you, nurses, whether this position is not a sufficiently lofty one, a sufficiently responsible one, to satisfy the ambition of any woman? Could any greater trust be imposed upon you, any greater confidence placed in you, if you were sculptor, actress, prima donna, lawyer, or physician?" The following is a summary of the annual report, which was read by Dr. Murray: The school was opened, in 1873, by thirteen women, to whom was intrusted the nursing of four wards in Bellevue Hospital. It now numbers sixty-four pupils, and has charge of 258 beds in fourteen medical and surgical wards, the Sturgis and Marquand Pavilions, and the Emergency Hospital attached to Bellevue. The school also nursed 125 private cases last year. Since its opening 105 nurses have been graduated, of whom twenty-five are engaged in hospital work, and 137 in private nursing. There were 813 calls for private nurses last year, of which 184 had to be declined, all the nurses being engaged at the time of application. Over 300 applications for entrance to the school were received, but only forty of the applicants were accepted. The expenses exceeded the receipts by $3,500, but two friends supplied the deficit. About a year ago the school was asked to furnish recruits for an association of trained nurses to be established in Rome, Italy, and on this occasion letters were read from there praising the work of the graduates sent.

Correspondence.

TREATMENT OF DISEASES OF THE EAR.

VIENNA, *January* 12, 1884.

MR. EDITOR, — Perhaps a few words concerning the treatment of diseases of the ear at the Vienna clinics may be of interest to some of your readers, and I will endeavor to mention some of the more interesting points in regard to it.

At all the clinics for simple otitis media purulenta uncomplicated by profuse granulations or polypi, after syringing and carefully drying the ear, very finely powdered boracic acid is blown in. This powder is allowed to remain until it becomes moist, when it is immediately syringed out, the ear is again carefully dried, and more powder is blown in. This should also be done by the patient at home as often as is necessary. As soon as the powder remains dry in the ear all treatment is stopped, and the powder gradually works its way out without the use of the syringe.

This treatment by means of powdered boracic acid has entirely superseded the use of astringent solutions, such as sulphate of zinc, alum, etc., which are now only used in exceptional cases where boracic acid has failed to check the otorrhœa. The results obtained seem to be very good indeed, and it is claimed that boracic acid is less irritating than the astringents, and that when properly prepared, that is to say, very finely powdered, it never forms hard masses in the ear which will act as foreign bodies, and so have to be removed. The best method of obtaining boracic acid of the proper quality is by precipitating it from a solution.

For cases complicated by granulations which are too small to be removed by the snare, and in the cases of children or adults who are frightened at the idea of being operated upon, spiritus vini rectificatissimi is used. The ear is to be filled with this fluid three times a day, and the alcohol is allowed to remain for from twenty minutes to half an hour, the patient in the mean time lying with his head upon a pillow. If alcohol in its full strength causes pain it should be diluted at first, and its strength increased gradually. Alcohol may be combined with the boracic acid treatment or it may be used after the removal of polypi by the snare. Larger granulations and polypi are removed by means of the snare, the sharp ring, or are touched with caustic.

Ferrum sesquichloridum is recommended as a caustic at all the clinics. It is better than nitrate of silver as it causes less pain and penetrates deeper into the tissues to be removed, and so accomplishes its object more quickly.

Urbantschitsch considers chromic acid, in its most concentrated form, the *very best caustic* to use for polypi or granulations, but it must always be applied through a speculum, and must not come in contact with healthy tissue, as when it does so it causes great pain. If granulations bleed after being touched with chromic acid a tampon of cotton wool must immediately be inserted in order to keep the acid from coming in contact with the walls of the external canal.

For tough fibrous polypi Urbantschitsch uses the galvano-caustic snare.

For both acute and chronic catarrh of the middle ear, besides the use of the air douche, catheter, etc., if the calibre of the Eustachian tube is diminished, bougies are passed through a catheter to the isthmus tubæ, and the canal is dilated up to the size of one and one third millimetres. In some cases these bougies are allowed to remain twelve hours in a ten per cent. solution of nitrate of silver, and then dried before being used. The ordinary bougies remain in the Eustachian tube about three minutes; those which have been soaked in nitrate of silver from a half a minute to a minute; but in any case if they cause sharp pain they are immediately withdrawn. Besides dilating the Eustachian tube they often act favorably in removing troublesome tinnitus, and it is not uncommon to find that after their use in one ear tinnitus of both ears is improved or ceases altogether. By reflex irritation of the acousticus through their use the hearing is also often improved, but it is doubtful how permanent this improvement is.

Another method employed to mitigate tinnitus, which is often so annoying, is the use of electricity. The constant current is at first tried, and if this fails to accomplish the desired end the induced current is used.

The anode (copper pole) is placed upon the tragus, and the kathode (zinc pole) is brought in contact with

some other part of the body, usually the side of the neck, or the hand. A very weak current is at first applied, and its strength is gradually increased, until the patient feels a sharp stabbing pain in the ear, or has severe tinnitus; the strength of the current is then gradually diminished, until it is once more at zero, *before removing the poles.*

The improvement due to electricity is sometimes permanent, — often only temporary, — and in some cases it has no effect upon the tinnitus.

But even in these last cases it often relieves the dull, stupid feeling in the head, loss of memory, etc., complained of by these patients; and in this way greatly improves their condition.

Electricity is also very often used by Urbantschitsch for otalgia, and gives very good, and in many cases permanent, results. For all recent cases of deafness due to labyrinthine disturbances, whatever the primary cause may have been, Politzer tries the subcutaneous injection of a two per cent. solution of the muriate of pilocarpine. He injects four drops at first, and gradually increases the dose to ten drops daily. He gets fairly good results in about one half of the cases.

I have seen three cases of persons totally deaf, who, after being treated in this way, could hear and understand loud speech spoken at the distance of a few inches from the ear; and Politzer has had one case of perfect recovery of the hearing after it had been absent for three years, and several other very satisfactory results, following the use of this drug. He is about to publish the results of his experiments, with the history of some of the cases. It is not known how pilocarpine acts in these cases, but the benefit derived from its use is certainly great in some of them.

It is considered here a part of the otologist's duty to examine and treat the nose and pharynx, to remove adenoid vegetations if they are present from the posterior nares, to cauterize the mouth of the Eustachian tube, etc.

For nasal polypi the ordinary snare, or the galvano-caustic snare, is used. For adenoid vegetations at the posterior nares the galvano-caustic snare, or Stoerk's snare constructed for this purpose, is employed to remove the growths, or else they are repeatedly touched with nitrate of silver, burned with the galvano-cautery, pulled off with forceps, or scratched out with the finger nail. In every case where the nose is found to be diseased, it is treated at the same time with the ear, and this is considered a very important aid to the treatment of the ear itself.

It is of course impossible within the limits of a letter, to do more than mention a few points in the treatment of diseases of the ear, and I hope that these may prove of interest to those of your readers who are otologists.

I remain, very truly yours,

H. L. Morse, M. D.

"PRECAUTIONS AGAINST CHOLERA."

Mr. Editor, — As an earnest inquirer, permit me to seek through the columns of the Journal answers to one or two questions suggested by a paragraph now going the rounds of the newspapers, entitled, "Precautions against Cholera."

(1.) Was there ever an authenticated case of cholera unmistakably introduced into this country by rags brought from abroad for manufacturing purposes?

Before the appearance here of cholera, half a century ago, and since, our best physicians preached and taught that it was non-contagious, and greatly calmed the fears of the people by their doctrines. "The history of cholera in our country," says one of the ablest of them, "has confirmed the correctness of these views." At any rate cordons have not been resorted to; segregation of the sick not insisted on. Instances there have been where the well have mingled with those attacked, even to the occupying the same bed with the dying, or one from which the dead had but just been taken. Often the clothing of the affected has been used promiscuously, without cleansing, by the family or the attendants. The dead have been buried, not hurriedly, in secret, but openly as usual; occasionally with public ceremonies in church, exposed there to the unrestrained view of friends and curious spectators, numbers of physicians standing by, and unconcernedly looking on. If any harm ever resulted from such procedures it has not been brought to light, or put any restraint on the free intercourse of the people.

(2.) If rags can carry cholera from one country to another, is there any known method, application, or process, whereby this baneful property when once acquired can be destroyed, — a *known*, not a theoretical, method?

Last year there was cholera in Egypt; and Egyptian ("cholera") rags brought to this neighborhood were unloaded in Boston Harbor, watered down with a medicated liquid, and then returned to the owners. What was the material so potential that applied superficially, penetrated and permeated the compressed bales, and deprived them of baneful power?

(3.) Apparently, however, not content with last year's methods, the government, according to the newspapers, proposes to carry on a cleansing process on its own account in Egypt itself, and the Boston Board of Health readily yields and gives the "action contemplated" its "hearty welcome." The Board says: "The rags being subjected to the boiling proposed (the newspapers do not tell what the "boiling proposed" may be), or to the action of confined sulphuric (sulphurous?) acid gas for six nours, burning one and a half to two pounds of roll brimstone in each one thousand cubic feet of space, with the rags well scattered upon racks, will be satisfactory to us."

Well, suppose all this practicable, ignorant people not unnaturally ask whether disease can be boiled out, and whether there is, in fact, any infection-destroying power in the fumes of burning brimstone? Moreover, if infection previously pervaded the rags, why may it not return to them when the pestilent air of Egypt, through and by which they originally acquired this infection, is again let in upon them before they are sufficiently dried or prepared to be baled up for transportation?

There would seem, Mr. Editor, to be a good deal of mistiness, if not of mistery, in such "precautions," as if coming *dark ages* cast their shadows before, and were already spreading their nebulous edges over the land. But outsiders should hold their peace until better informed. In the hope of further enlightenment the foregoing questions are tentatively asked.

Inquirer.

— In Vienna, in 1882, there were 16,605 births in wedlock, and 12,657 illigitimate.

Miscellany.

A NEW METHOD FOR THE DETECTION OF THE BACILLUS TUBERCULOSIS.

DR. HARTZELL, in the *Philadelphia Medical Times* (January 26th) describes a new method for discovering the bacillus, which he claims has advantages over most of those hitherto in use. It is as follows: —

A small quantity of sputum is spread as thinly and evenly as possible upon an ordinary glass slide; it is allowed to dry, which takes but a minute or two, and is then passed slowly several times through the flame of an alcohol lamp or Bunsen burner. One or two drops of the fuchsin solution, recommended by Gradle, and prepared as follows, — carbolic acid, fifteen minims; distilled water, one half fluid ounce; dissolve, and add saturated alcoholic solution of fuchsin, one half fluid drachm, — are placed upon the sputum thus prepared, and allowed to remain from three to five minutes. The slide is now washed thoroughly with distilled water, to remove the excess of fuchsin, and the stained sputum completely decolorized by means of a saturated solution of oxalic acid. It is again thoroughly washed in distilled water, after the decolorization, and allowed to dry; it is now ready to be mounted in glycerine or balsam for examination. With a power of five hundred or six hundred diameters the bacilli will appear as brilliant red rods, no staining of the background being necessary.

One chief advantage claimed over other methods is that in the latter the decolorizing agent employed is dilute nitric acid; but this, besides being disagreeable to handle because of its corrosive and staining properties, is apt to remove the color from the bacilli too, unless great care is taken. Oxalic acid, however, seems to leave the dye untouched in them.

THE LATE DR. CALVIN ELLIS.

AT a meeting of the Medical Faculty of Harvard University, held February 2, 1884, the Dean, Dr. H. P. Bowditch, presented the following tribute to the memory of the late Dr. Calvin Ellis, prepared at the request of the Faculty by Dr. O. W. Holmes, and it was voted to enter the same on the records of the Faculty, and to transmit copies to the sister of the deceased, and to the editor of *The Boston Medical and Surgical Journal* for publication: —

For nearly a quarter of a century Dr. Calvin Ellis has been connected with the Medical School of Harvard University. He had been recognized while a student as a young man of great promise, endowed not only with superior abilities but with the sterling elements of character which enable those who know the student to predict his future success with no misgivings.

He began early his professional life, giving his especial attention to the subject of morbid anatomy, following in the steps which had marked the long and patient career of our lamented friend, the late Dr. James Jackson. This branch of science involves great labor and self-sacrifice, and repays them with an exact knowledge of the nature and course of disease not to be obtained by any easier method of study. His devotion to this arduous pursuit laid the foundation in science of the skill which he carried into the art of healing, and of his success as a teacher of pathology and of clinical medicine.

Dr. Ellis took an active and never flagging interest in all that related to the administration of the Medical School of the University. He had a special care for the microscopic department, which was largely developed under his influence, and for the use of which he made a gift in 1872 of five hundred dollars. From 1869 to 1883 he was dean of the Medical Faculty, and discharged all the duties of that office with the fidelity which he carried into whatever he undertook. It is now several years since he began to suffer from the disease which caused his death. Even after this disease had greatly impaired his active powers he would still attend the meetings of the Faculty, and when at length he was missed from his usual place those who knew him felt that he was doomed, for no less than some imperative hindrance could keep him from being with them.

His long period of suffering bravely borne has at last come to an end, and he has left us to mourn the loss of a precious life cut off in the midst of its usefulness. Of that diligent, faithful, honorable life this Faculty has reaped some of the best fruits. His memory will always be gratefully cherished by those who have been associated with him in the work of medical education, and they leave on record for those who come after them this affectionate tribute to the virtues and talents of their able, upright, noble-hearted colleague and friend.

SOME SURGICAL USES OF COLLODION.

MR. SAMPSON GAMGEE, in the *Birmingham Medical Review* (January, 1884), mentions some uses of this therapeutic agent which he thinks is not in general sufficiently appreciated or utilized. He remarks, that being composed of ether, gun-cotton, and spirit, collodion is a powerful anti-putrescent; and, by ready evaporation and contraction, it exercises the dual antiphlogistic power of refrigeration and compression.

In acute orchitis he knows no plan of treatment so simple, rapid, and satisfactory, as coating the cord and scrotum with layers of collodion, by the aid of a camel-hair brush previously dipped into it. The sensation is momentarily sharp, the shrinkage rapid, and so is the subsidence of the inflammatory process.

To swollen parts which cannot well be bandaged, collodion is especially applicable for the compression attending its contraction. The author was consulted in the case of a good looking boy considerably disfigured by a red and swollen nose, which became very pale and visibly contracted just after being painted with successive layers of collodion. The application was repeated three times in the succeeding fortnight, with the effect of producing shrinkage of the organ to its natural size and color.

When the nasal bones are fractured, Mr. Gamgee recommends as a very effective mould for keeping them immovable, after adjusting them with the fingers, the following: Place over the nose a thin layer of absorbent cotton soaked in collodion; as it dries another layer of cotton and more collodion, taking care that the application extends sufficiently on each side to give buttress-like support. The patient compares the feeling to the application of a firm bandage on the nose, and the bones consolidate effectively under the shield, which may be renewed as it cracks and peels off.

In the dressing of fresh wounds, the author speaks

highly of the same agent, to be applied after thoroughly drying the surface. Its effect is also good when applied in other than fresh wounds, as in a case cited where a man had suffered for ten days from a wound of the shin inflicted by a carriage-step. Water dressing had been applied continuously, and the surface of the sore had suppurated, and its edges for some distance around were red and tender. The limb was raised to empty it of blood, dried with an absorbent, and painted with collodion, then bandaged, and cicatrization was perfect in four days, the patient having sustained no interruption of his use of the leg.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 2, 1884.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2624 (no reports from New Orleans and Buffalo): under five years of age, 922: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 388, lung diseases 455, consumption 405, diphtheria and croup 141, typhoid fever 54, scarlet fever 44, measles 40, diarrhœal diseases 25, erysipelas 23, cerebro-spinal meningitis 17, malarial fevers 13, puerperal fever 15, whooping-cough 13, small-pox two, typhus fever one. From *measles*, New York 13, Philadelphia 10, District of Columbia nine, Brooklyn seven, Boston one. From *diarrhœal diseases*, New York six, Boston four, Philadelphia and Brooklyn three each, St. Louis, Cincinnati, and New Haven two each, Baltimore, District of Columbia, and Milwaukee one each. From *erysipelas*, New York seven, Philadelphia, and Boston three each, Brooklyn, Chicago, St. Louis, Cincinnati, and Charleston two each, District of Columbia one. From *cerebro-spinal meningitis*, Worcester three, New York, Chicago, Cincinnati, and Lowell two each, Boston, Fall River, Springfield, Salem, Holyoke, and Brockton one each. From *malarial fever*, New York and St. Louis four each, Brooklyn and Baltimore two each, Chicago one. From *puerperal fever*, New York, Chicago, and St. Louis three each, Boston two, Providence, Cambridge, and Philadelphia, one each. From *whooping-cough*, New York four, District of Columbia three, Chicago two, Brooklyn, Boston, St. Louis, and Fall River one each. From *small-pox*, St. Louis and Cincinnati one each. From *typhus fever*, Philadelphia one.

Seven cases of small-pox were reported in St. Louis; scarlet fever 47, diphtheria 30, typhoid fever four, and measles three in Boston; scarlet fever seven and diphtheria three in Milwaukee.

In 92 cities and towns of Massachusetts, with an estimated population of 1,319,769 (estimated population of the State 1,922,530), the total death-rate for the week was 16.59 against 17.78 and 20.00 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 19th, the death-rate was 20.7. Deaths reported 3479: acute diseases of the respiratory organs (London) 395, whooping-cough 117, scarlet fever 108, measles 100, fevers 61, diphtheria 28, diarrhœa 27, small-pox (Sunderland six, London five, Birmingham and Liverpool four each) 19. The death-rates ranged from 11.3 in Wolverhampton to 26.7 in Manchester; Bradford 17.2; Nottingham 18.8; Newcastle-on-Tyne 19.3; Leeds 19.8; Birmingham 20.3; London 20.5; Liverpool 20.7; Leicester 22.8; Sunderland 23.3; Sheffield 25. In Edinburgh 20.3; Glasgow 26.1; Dublin 26.9.

The meteorological record for the week ending February 2d, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

RESOLUTIONS ON THE LATE DR. GEORGE C. LAWRENCE.

THE following resolutions were unanimously adopted at the meeting of the Berkshire District Medical Society, held at Pittsfield, January 30, 1884: —

Whereas, It has seemed best to the Supreme Ruler to remove from our midst our brother, George C. Lawrence, of North Adams.

Resolved, That while we bow with submission to the Divine will, we still in the death of our beloved brother deplore the loss of an earnest and faithful physician, temperate and true in his professional obligations, towards his brethren courteous and honorable, while progressive, not radical, thoroughly loyal and sincere in his professional work.

Resolved, That we tender to his family our sincere sympathy in their sudden loss of a kind and faithful husband and father, and to the community in which he practiced of a laborious, studious, and self-sacrificing physician.

Resolved, That a copy of these resolutions be sent by the Secretary of this Society to the family of our deceased brother, and to the papers of North Adams, *The Boston Medical and Surgical Journal*, and also be placed on the records of this Society.

A. M. SMITH, Williamstown,
H. M. HOLMES, Adams,
H. J. MILLARD, No. Adams,
N. S. BABBITT, No. Adams,
A. M. SMITH, Pittsfield.
} *Committee.*

DEATHS.

DIED, in Pittsfield, Mass., February 6th, Almon N. Allen, M. D., aged sixty-three. He was a native of Petersburg, N. H., a graduate of the Albany Medical College, and had practiced in Pittsfield over thirty years. He was a member of the Massachusetts Medical Society since 1861. He leaves a widow, and a son, who is a physician in Brooklyn.

Died, in Great Barrington, Mass., February 5, 1884, Noble Bennett Pickett, M. D., M. M. S. S., aged eighty-three years.

A BILL TO PREPARE AND PUBLISH A NATIONAL PHARMACOPŒIA FOR THE UNITED STATES.

IN the House of Representatives, January 8, 1884, Mr. Randall introduced a bill, as follows, to prepare and publish a national pharmacopœia for the United States, which was referred to the Committee on Ways and Means: —

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled: —

That the Secretary of the Treasury shall, as soon as practicable, detail two officers of the Marine Hospital Service, and the Secretary of War shall detail two officers of the Medical Staff of the Army, and the Secretary of the Navy shall detail two officers of the Medical Staff of the Navy, for the duty of compiling and preparing a pharmacopœia, which shall be known as the National Pharmacopœia of the United States of America, and shall be held and accepted as the standard for the purveying, compounding, and dispensing of drugs or medicinal agents, and shall be taken as authority in the Treasury Department on all questions arising under the tariff laws of the United States with regard to the nomenclature, description, and purity of drugs or remedial agents, and shall further be received as evidence in the United States courts. And the matters contained in the said pharmacopœia shall be free for use by all authors and commentators for the benefit of the medical and pharmaceutical professions and of the community at large; and it shall not be lawful for any one to reprint and publish the said pharmacopœia as a whole.

SECT. II. That the medical officers detailed as above provided shall invite the American Medical Association and the American Pharmaceutical Association, at their next annual meetings, to form committees of not more than three members from each of the said Associations, which committees, if so appointed, may coöperate with the above-named medical officers in the preparation of the said pharmacopœia, forming a board which shall have power from time to time to add to its number as may in its judgment be necessary, and which shall elect a chairman and a secretary, and adopt such rules as it shall see fit for the expediting and perfecting of the said pharmacopœia, which, when completed, shall be printed under the supervision of the said board; and an edition of not less than five thousand copies shall be printed for use in the several departments of the government of the United States; and copies may be furnished to private persons in accordance with the provisions of section thirty-eight hundred and nine of the Revised Statutes.

SECT. III. That for the purpose of defraying the necessary expenses of preparing the said pharmacopœia the sum of five thousand dollars is hereby appropriated out of any moneys in the treasury not otherwise appropriated, and the same shall be disbursed under regulations to be prescribed by the Secretary of the Treasury.

SECT. IV. That the said pharmacopœia shall be revised once in ten years, upon the plan embodied in this Act.

THE WINTER CLIMATE OF NEWPORT.

AT a regular meeting of the Newport Medical Society, held February 5th, at which twelve members were present, it was

Resolved, That the Newport Medical Society indorses the opinion advanced by Dr. H. R. Storer, that the winter climate of Newport is preferable to that of the rest of New England for certain forms of pulmonary diseases, and for general invalids, provided that when here the patients are under proper hygienic conditions as regards location, etc.

THATCHER GODDARD, M. D., *Secretary.*

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING FEBRUARY 9, 1884.

VAN REYPEN, W. K., surgeon, from the U. S. S. Powhatan, to the Navy Department as assistant to the Bureau of Medicine and Surgery, and acting chief of that Bureau.

HOEHLING, A. A., surgeon, from special duty at Washington to the Powhatan.

Original Articles.

ON THE TREATMENT OF ACUTE PNEUMONIA.[1]

BY FRANCIS MINOT, M. D.

Notwithstanding the great improvement which has gradually taken place in the treatment of acute pneumonia during the last thirty years, I think it is not yet so perfect as our knowledge of the pathology and course of the disease should lead us to expect. Although the belief that it is essentially an inflammatory disease is fast disappearing, the traces of the mode of treatment founded on that theory still remain. It is true, we do not often bleed our patients, nor give them tartar emetic, nor purge them actively; but it is not uncommon to see extensive blisters applied to the chest, and aconite, veratrum, and other sedatives are given with a view of diminishing the rate of the pulse, and thereby, it is argued, of reducing the inflammation, while, strange to say, nourishment and stimulants are freely given at the same time to support the strength. It is only recently that the notion of the infectious nature of pneumonia, first maintained, I believe, by Juergensen, of Tübingen, began to be accepted by well educated and experienced physicians, and it is natural that the traditions of a former generation, which believed in its essentially inflammatory character, should still prevail among us. If it were more generally known that the disease is self-limited and infectious, as much so as measles or variola, and that it is rarely if ever fatal in healthy subjects, a more rational treatment would be substituted for the complicated and frequently contradictory one so often seen employed.

For the sake of convenience I will divide the subject of the treatment of pneumonia into three sections. The first section relates to cases occurring in healthy persons, without distinction of ages. The disease is almost never fatal, and rarely attacks both lungs. The initial stage of the fever occupies from twenty-four to forty-eight hours; the fastigium, during which the temperature does not rise above 104° F., usually lasts seven days, at the end of which time the temperature suddenly falls to the normal point, or a little below it, the crisis occupying one, two, or rarely three days. (See the Charts Nos. 4, 5, and 6.) The ratio between the rate of the respiration and that of the pulse (normally, one to four and a half) is not greater than one to three. There is but little appetite, and in young children usually none. An experience of many years in hospital and private practice has convinced me that these cases always do well without any special treatment, medicinal or dietetic. Sometimes an anodyne (Dover's powder or morphia) or a sedative (bromide or chloral) is useful to relieve pain or restlessness, or the solution of the acetate of ammonia may be given if the skin be hot and dry. As much water, not iced, should be allowed as the patient desires for drink. External applications are not needed, and all irritating epithems should be avoided, since counter-irritation only adds to the patient's suffering without modifying the self-limited process usually considered as "inflammation" of the lung. I am decidedly opposed to the application of poultices to the chest, especially "jacket" poultices. The fatigue and exposure caused by their frequent changing, and by their removal for the purpose of auscultation and percussion, are injurious; they are uncleanly, and possess no advantage, in my opinion, over a woolen jacket or waistcoat, or still better, one extemporized out of a sheet of wadding (not batting), to satisfy the prejudices of the patient's friends, who are too often, as in other cases, unconsciously his enemies. I would plead for little children, who like nothing so well as to be left undisturbed by officious ministration, requiring no nourishment beyond a little milk, with water at discretion. When the crisis comes food is readily taken.

If possible, the patient should lie on a single bed, so as to be easily handled by the nurse and physician. His clothing should be no heavier than is agreeable to him. Fresh air should be constantly admitted to the room, and a fire should be kept burning in the fireplace day and night, except when the weather is warm enough for open windows.

As to diet, the patient should not be urged to take more food than he likes. It is a common idea that he is in danger of sinking from exhaustion, and must be sustained by being constantly crammed with beef tea, milk, gruel, etc. In reality very little food is necessary during the short period of the acute stage, and nature declines to digest more than a small quantity, frequently rejecting from the stomach what has been swallowed. In the case of children, particularly, I have observed that there is a strong objection to taking nourishment, and that when this instinct is respected the patient does perfectly well; as soon as the temperature falls he asks for food. But I find great difficulty in making parents and nurses believe this, owing to a natural application of the modern supporting treatment, so useful in typhoid fever and other exhausting diseases, to acute and transient affections.

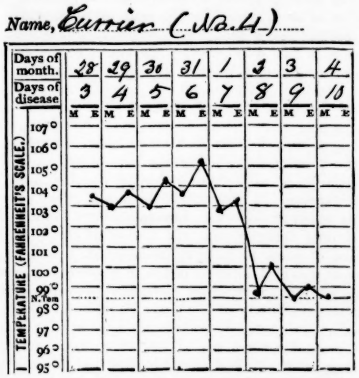
The second class of cases of pneumonia include those occurring in healthy subjects who are debilitated from various causes, such as old age, overwork, previous illness, etc. They are free from cachexia, and under appropriate treatment the majority recover, but the prognosis is much more doubtful than in the preceding class. The disease is apt to extend from one lung to the other (though this is by no means always fatal), the temperature falls more gradually than in uncomplicated cases, and convalescence is often more prolonged. The treatment should not, in my opinion, differ materially from that just described, except that alcohol is usually required, and digitalis is necessary if there should be signs of pulmonary obstruction from failure of the heart's action. Champagne usually agrees very well, but any other stimulant, if preferred by the patient, will answer. Brandy and carbonate of ammonia must be given when there is much exhaustion.

The third class of cases comprise those which occur in cachectic individuals. The great majority of the patients die, whatever treatment be adopted. They are generally intemperate, or are victims of chronic renal disease, or they are tuberculous; but patients already prostrated by grave acute disease, such as typhoid fever, variola, bronchitis, etc., although otherwise previously healthy, when attacked by pneumonia may also be unable to resist the intercurrent disease. The stage of hepatization is succeeded by purulent infiltration, and sometimes by gangrene, and death follows from asphyxia and exhaustion, usually with very high temperature, though sometimes without much elevation, as happened in two of the cases which I shall report. (See the Charts No. 7 and No. 9.) In these cases

[1] Read before the Boston Society for Medical Improvement, February 10, 1884.

stimulants should be freely given; large doses of brandy are easily borne, and sometimes appear to save life. Nourishment in liquid form is also required, but seems less important than alcohol. External applications, those at least which require frequent changing, should be avoided, as the patient has no strength to spare.

The following cases, appended in illustration of the above remarks, were treated by me in the Massachusetts General Hospital, during the latter part of the winter and spring of 1883:—



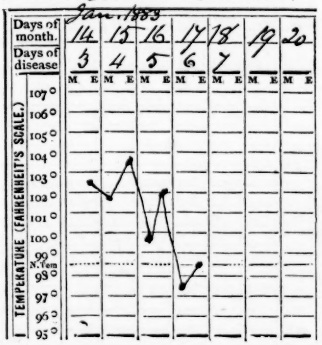
CASE I. Ellen Egan, forty-six, single, domestic. She had had rheumatic fever eighteen and ten years previously; otherwise her health was good. Entered January 2, 1883. Two days previously she had a chill, followed by pain in the left side, cough, and brownish expectoration. There was considerable dyspnœa. Temperature 103.5° F., pulse 110, respiration 40; adhesive, rusty-colored sputa; no cardiac murmur; signs of solidification in lower portion of left lung. On the third day after entrance physical examination showed almost complete solidification of the left lung; respiration 52, and labored; face dusky, cheeks deeply flushed; pulse 124. The temperature, however, was only 102° F. (Carbonate of ammonia, brandy.) From this time the symptoms gradually improved, and on January 13th, eleven days after entrance, and thirteen from the beginning of the attack, she was convalescent. Discharged January 31st, four weeks after entrance. This case would come under the second class. The patient was of a healthy constitution, but was probably exhausted by hard work and the unfavorable hygienic conditions to which domestics are often subjected. The pulmonary congestion was relieved by stimulants, and she recovered after an illness of moderate duration.

CASE II. Tim. Murphy, twenty-nine, good general health and family history. Pneumonic seizure six days before entrance. Entered January 4, 1883; pulse 94, temperature 101° F., respiration 30. Cough; rusty, adhesive sputa. On the third day after entrance temperature was 103.4° F.; the next day 99.8° F., and it gradually fell till the eighth day after entrance, when it became normal. Repeated examinations of the chest were made, but nothing abnormal was ever found. The urine showed a trace of albumen. He took no stimulants, and no medicine, except a little of the solution of acetate of ammonia. He was discharged, well, January 26th, twenty-two days after entrance. This case was one of the mildest sort. The disease was probably central, and so escaped observation by physical signs, but the history, the temperature, the expectoration, etc., were enough to establish the diagnosis. No treatment was required or given.

CASE III. J. Avery, forty-one years, mariner, entered January 17, 1883. General health and family history good. Two days before entrance he had a chill, followed by pain in left side and back, increased by long breath, cough without expectoration, headache, and pain in limbs. Temperature 103° F., pulse 112, respiration 32. No râles and no friction sounds were heard. Two days after entrance the temperature was normal, there was a little bloody expectoration, and evidence of consolidation at the left apex. On the 23d he had an attack of tonsillitis, lasting a few days, but on the 31st all his symptoms disappeared, and he was discharged, well, fourteen days from his entrance.

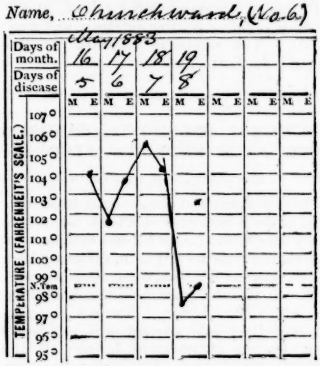
It is not certain whether this really was a case of pneumonia, though so entered on the hospital books. There was evidently a pleuritic complication, and possibly a tubercular deposit in the left apex. The treatment consisted in fomentations to the chest, Dover's powder, and spirit of nitrous ether. For the tonsillitis cold applications to the throat, with an astringent gargle, were ordered.

CASE IV. William Currier, twenty-six years, horse-car conductor, American. One sister died of consumption.



He had always been well, and had had no unusual exposure to cold or wet. Entered January 28, 1883. Two days previously he had a chill, with pain in every part of the body, but especially in the right side of the chest, where it was increased by deep inspiration or cough. There was dyspnœa, cough, reddish, sticky, expectoration, a little nausea and vomiting, and debility. Temperature 103.4° F., pulse 130, respiration 28. Dullness and fine crepitation in lower part of right chest, behind and at the side. The temperature fell to normal between the evening of February 1st and the morning of February 3d, — six and one half degrees. He then improved rapidly, and was discharged, well, February 9th, twelve days after entrance, and on the fourteenth day of the disease.

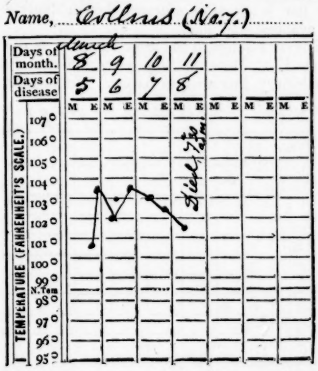
The temperature curve (Chart No. 4) will be seen to be typical. For treatment he had at first hot fomentations, with Dover's powder. February 1st he was ordered four drops of tincture of aconite every four hours with an ounce of whiskey. I do not think I could have been responsible for this strange combination, which may have been directed through inadvertence by the house pupil. The aconite evidently did no harm, but probably no good either.



CASE V. Michael O'Connor, twenty years, laborer, landed in Boston, from Ireland, May 6, 1883, well. On the 9th he had headache, vomiting, cough, and dyspnœa, but there was no definite history of chill. He entered the hospital May 14th, with a temperature of 102.2° F., pulse 100, respiration 32. Face flushed, dullness, and bronchial respiration in lower third of left lung, and a limited area of fine crepitant râle. Sputa orange-colored, tenacious, and scanty. The following evening the temperature rose to 103.4° F., the highest point; then, in forty-eight hours, it fell to 97.5° F., and convalescence began. He was discharged, well, June 2d, nine days after entrance, and twenty-four days from the first symptoms. The treatment consisted in

Dover's powder, an occasional opiate for his cough, and whiskey.

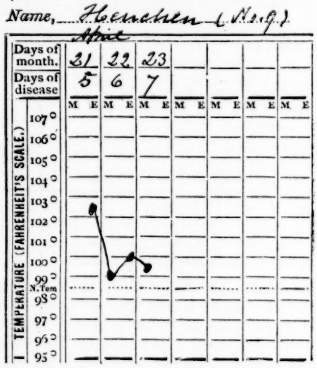
This patient entered just at the end of the second stage, the most fortunate moment for a favorite remedy, for the change was sure to follow whatever should be given, or, as in this case, if nothing were given.



CASE VI. James Churchward, born in the Isle of Jersey, thirty-two years, married, coachman. One brother died of consumption. Health always good; habits good. May 11th, after exposure to wind while driving, chilly sensations; next day sharp pain in left side, increased by drawing long breath, slight cough, and bloody expectoration. He entered May 16, 1883; temperature 104° F., pulse 106, respiration 36. There was a soft, direct aortic murmur, propagated into the carotid; also a soft diastolic murmur, in the same place, extending downward and across towards apex. Dullness in lower half of left back, with abundant fine crepitant râle. Expectoration brownish, adhesive, and scanty. On the 18th the temperature was 105.2° F. In twenty-four hours it fell to 97.8° F., a difference of 7.4° F., and convalescence began. Abundant friction sounds were heard in the left back and side after the pneumonic resolution. On the 17th the urine contained a slight trace of albumen, but no casts; chlorides diminished. June 1st he was discharged, well, sixteen days after entrance, and twenty-one days from the first symptoms. He took Dover's powder, a little morphia, the solution of the acetate of ammonia, and tincture of cinchona.

This patient entered just before the crisis, and consequently his rapid recovery might easily have been attributed to any treatment which happened to be employed. It is interesting to note that neither the condition of aortic insufficiency, perfectly compensated, indeed, nor a family history of consumption, had any unfavorable effect upon the course of his disease, which was typical. He was at first somewhat concerned because a "jacket poultice" was not applied, which he had always heard was the legitimate treatment for pneumonia. But he admitted that he was very comfortable, and on his departure expressed much gratitude for the relief he had obtained.

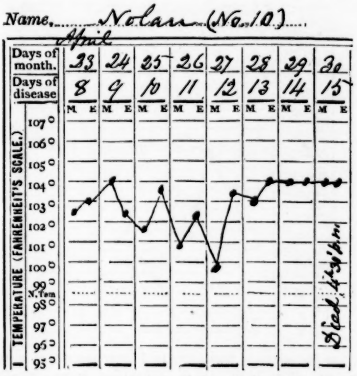
CASE VII. Tim Collins, sixty years, longshoreman, widower. Family history said to be good. He had chills and fever several years ago, "typhoid fever" twelve years ago, and pleurisy of the left side eight years ago. Dyspnœa on exertion, debility, and loss of appetite for a year past, but he had kept on working. March 3d and 5th, respectively, he "vomited blood," but had no other gastric symptom. He had cough for two weeks, especially at night, which increased since the 5th. No chill. Entered March 8, 1883. Temperature 100.8° F., pulse 112, respiration 30. Face flushed; heart sounds very faint. Dullness in right side, with abundant dry crepitation; slight crepitation also below left nipple; no bronchial respiration heard; copious, adhesive, orange-colored sputa. The patient was too much prostrated to bear much examination. He failed rapidly, and died early in the morning of the 11th, three days after entrance. The temperature rose to 103.8° F. on the evening of the 9th. At the time of his death it had fallen to 101.6° F. The treatment consisted in stimulants and nourishment. The autopsy showed almost complete solidification of the right lung, a small amount of hepatization in the upper front of the left lung, the lower lobe œdematous and injected, with evidence of old pleurisy of the same side. The rectus abdominalis and numerous other muscles were infested with calcified trichinæ.



The discovery of calcified trichinæ in the muscles is interesting in connection with the history of "typhoid

fever" twelve years previously, which had been evidently mistaken for the parasitic disease. The patient, like many of his occupation, was probably intemperate, and broken down by previous disease, and the case comes under the head of pneumonia in cachectic individuals. The only hope lay in active stimulation. As is not very unusual in such cases, the temperature was moderate, at least while he was under observation.

CASE VIII. McKeon, forty-four years, laborer; of good family history; said to have been a moderate drinker. No history of previous lung trouble. April 9, 1883, he fell into a cellar, injuring his left side. Twenty-four hours later he had a chill, cough, dyspnœa, pain in the left side, and diarrhœa. Entered April 15th, having walked half a mile to the hospital. Temperature 100° F., pulse 100, respiration 50. He was cyanotic, and could not breathe lying down. There was consolidation of lower part of left lung, with coarse moist râles over both backs and fronts. Tenderness in left hypochondrium. Sputa abundant, and of a dirty-chocolate color. His condition improved somewhat after whiskey and pilocarpine were given, but a few hours after entrance he suddenly became more cyanotic, and died.



This case belongs to the same category as the last.

CASE IX. Henchy, fifty years, laborer, phthisical family history, intemperate habits. No previous lung

trouble. Five days before entrance general symptoms, with pain in the side, cough, rusty-colored sputa; no chill. Entered April 21, 1883; temperature 102.5° F., pulse 100, respiration 50. Subsultus, rapid and labored breathing, and small pulse; abundant, frothy, dark-brown sputa. Consolidation of lower lobe of left lung. The next day the temperature fell to 99° F., but the general condition was decidedly worse, and in spite of the free administration of stimulants he gradually failed, and died April 23d, the third day after entrance, and eighth of disease. (Same class as the preceding case.)

CASE X. Matthew Nolan, thirty-six years, teamster, married, said to be of intemperate habits. Entered April 23, 1883, having had a chill six days before, followed by pain in the left side, with cough and yellowish expectoration. He was much prostrated, and somewhat delirious. Temperature 102° F., pulse 96, respiration 39. Dullness, with bronchial respiration, in left front, from top to seventh rib. In upper part, also, coarse râles, and in lower fine dry râles. Corresponding signs in left upper back. Urine contained a trace of albumen; chlorides diminished; no casts. The delirium and prostration increased, and he tried to get out of bed. The temperature, which rose to 103.7° F. the day after entrance, fell gradually to

99.8° F. on the morning of the 27th (fifth day after entrance and eleventh of disease). The same evening it rose to 103.5° F., and on the following evening to 104° F., where it remained till his death, at 4.30 P. M. of the 30th, eighth day after entrance and fourteenth of disease. The treatment consisted in stimulants, opiates, and nourishment.

"INFECTIOUS" PNEUMONIA, GANGRENE OF LUNG, FETID EMPYEMA. RECOVERY.[1]

BY HENRY W. BROUGHTON, M. D. (HARV.), OF JAMAICA PLAIN.

ANYTHING which can throw light upon the vexed question of the causation of disease is important. The following case seems to have been modified by, if indeed, it did not have its origin in, defective drainage.

Mrs. S., aged twenty-nine, the mother of several children, was at time of present illness a healthy, stout woman, with a good history. She had complained for a week of a slight cold accompanied by backache and malaise. On the afternoon of January 19, 1882, she was seized with a sharp chill with subsequent fever and sweating. This was followed by a second chill during the evening, a third equally severe on the following morning, and again a fourth on the next day. Her cough meanwhile increased, while sharp pain was felt in right side, aggravated by respiration. When first seen, on third day of illness, she was in bed, breathing with difficulty because of pain. Tongue covered with pasty coat. She had a short cough, with slight, whitish expectoration. Pulse 120; temperature 102.4° F. A physical examination disclosed dullness at base of right lung behind, with explosions of fine crepitant râles at end of inspiration. No friction sounds were heard. During the following two weeks the patient experienced a severe attack of acute croupous pneumonia, which involved the middle and

[1] Read before the Norfolk District Medical Society, December 20, 1883.

lower lobes of right lung. In the first and second stage, the disease was apparently typical, with the exception of the frequent rigors at the outset. One trying and dangerous episode occurred on the fifth day, to which I ought to allude, as it nearly terminated the case. Pain in the side was a distressing and prominent symptom.

A mixture containing tr. verat. viridis, tr. opii and nitre failed to control pain. I therefore felt obliged to order morph. sulphat., one fourth grain, in pill, to be repeated in three hours if there was no relief. On the next morning I found that the nurse, usually efficient and intelligent, had continued the morphia until one and one fourth grain had been taken. The patient was consequently in extreme peril. She was only rescued from lapsing into a fatal coma by vigorous effort. Brandy was administered subcutaneously, with whiskey and strong black coffee by mouth. Atropia sulphat., one thirtieth grain, was also given. After five hours of great anxiety on my part, she was out of danger as far as the morphia was concerned. The patient bore this ordeal well. Nothing abnormal was observed in the further progress of the pneumonia until the third stage was reached. It then became apparent that normal resolution of the solidified lung was not to occur. Upon the eighteenth day of illness the expectoration, which had been rusty and free, began to have a distinctly fetid odor, and a day or two later it became dark, like prune juice, with an extreme fetor. This unwelcome sign was accompanied by a recurrence of chills, an increase of fever, and marked asthenia. Coarse, moist râles were heard over the right back. For a week or ten days this condition continued. Expectoration was at intervals dark in color, almost black, and intensely fetid. At other times it was simply rusty or white with slight fetor, and occasionally tinged with bright red blood. In spite of free stimulation and the use of tonics and a generous diet, she was losing ground. It seemed probable, therefore, that there was somewhere in the affected lung a circumscribed gangrene.

There had thus far been no evidence of pleurisy, but on the fortieth day (February 28, 1882) there was positive evidence of an effusion into the pleural sac of the affected side (right). Chills again recurred with fever. The expectoration became more profuse, being still intensely fetid and dark colored. Sweet breath was also observed.

We therefore had to contend with a partially solidified lung, a portion of which was gangrenous, and a suppurative pleuritis, with a decomposition of the contained pus. The patient was rapidly sinking.

After consulting with Dr. Henry I. Bowditch and Dr. F. H. Williams I performed paracentesis. Twenty-two ounces of very thick, fetid pus were withdrawn. The fluid was at first gelatinous and mixed with bubbles of gas. Her strength at once began to improve, and in three or four days, when the chest gave evidence of refilling, a permanent opening was made, under strict antiseptic precautions, by Dr. A. T. Cabot, Drs. Bowditch, Williams, and myself assisting. This occurred on March 5, 1882, the forty-fifth day of illness. From fifteen to twenty ounces of thick, fetid pus were washed away. In two weeks the tube was removed, and a few days later the opening was healed. The patient's condition was now a hopeful one. The lung was beginning to expand, and a rapid convalescence seemed probable. Two events, however, occurred to retard this convalescence. The first was the sudden death of her father, which occasioned an intense mental shock. Secondly, after she had begun to sit up, and had even walked a few steps, she was suddenly startled by the crash of a falling lamp in the kitchen on the same floor. In great terror, and without aid, she ran to the scene to rescue her children. This effort utterly prostrated her. For more than a year she was unable to walk a step alone. Eight months after her illness, while still a cripple, she became pregnant, and in due time gave birth to a puny child who lived but a few days. From that date to this she has steadily improved in health, being now able to walk alone, and is making rapid progress.

In looking at the case in retrospect we remember that a young and healthy woman is attacked with pneumonia. The disease instead of pursuing a normal course presents several peculiarities. (1.) We recall that the onset, instead of being ushered in with the usual initial chill, is attended by several successive and severe rigors. (2.) We observe that the stage of resolution, instead of taking the normal course of ordinary pneumonia, is modified. Slight fetor of breath and of expectoration is noticed upon the eighteenth day, which is soon intensified, giving evidence of a circumscribed gangrene within the affected lung. (3.) After three weeks more a purulent effusion is found in the pleuritic cavity. Chills and rise of temperature indicate the decomposition of the contained fluid. The patient is sinking rapidly but is rescued by the operation for permanent opening.

In a discussion of this rare case many interesting and important questions might arise. We will, however, consider but one, namely, the ætiology. It would naturally be asked if there were not a discoverable cause for this abnormal and exceptional modification of simple acute pneumonia.

In order to answer this inquiry it will be necessary for us to investigate certain circumstances attending the illness. The family to which my patient belonged consisted of nine persons: a father, two daughters with their husbands and children. From October 17, 1881, to April 2, 1882, a period of six months, seven cases of sickness successively appeared in this family. With the exception of the first, I attended them all. Of these seven cases, four were ill with what, for convenience, I call febricula. They closely resembled one another both in the number and sequence of symptoms. The differences were those of degree or intensity. They were all preceded by headache or malaise, perfectly well marked, which constituted a prodromic stage. The attack in each of these four cases was ushered in by a distinct rigor, or by chilly sensations at least. Pyrexia followed with the nervous symptoms of pain in the back and head, nausea, etc. It is important to note that during the attacks there was a somewhat unusual constitutional depression, suggesting systemic blood-poisoning. Lastly, in each of these cases of febricula, there was a tardy convalescence, debility, and more or less anæmia persisting for several weeks, and in one case for a year (Case VII.). This is the familiar phenomenon after diphtheria and other infectious diseases. In addition to these four cases of febricula a girl, aged fourteen, was seized, on November 13, 1881, with what was reported by the physician in attendance to be typhoid fever. I saw the case just before death. The disease ran a rapid course and resulted fatally in five days. Next in the series was the case of pneumonia

with gangrene and empyema; and six weeks later the father of the family, an old man, was taken ill with phlegmonous erysipelas. This began in the subcutaneous connective tissue of the back of the neck. The disease commenced with a chill, and soon a diffuse and severe inflammation involved the whole posterior aspect of the neck and shoulders. The temperature reached 104° F. The patient rapidly became delirious, then comatose, and died on the third day, before suppuration had become established, succumbing to the septic influences of the inflammation.

Case I.	Oct. 17, 1881.	Febricula.	Three days.	Recovery.
Case II.	Nov. 13, 1881.	Typhoid fever.	Five days.	Death.
Case III.	Jan. 19, 1882.	Pneum., gang., empy.	Two years.	Recovery.
Case IV.	March 14, 1882.	Phlegmon. erysipelas.	Three days.	Death.
Case V.	March 15, 1882.	Febricula.	Two days.	Recovery.
Case VI.	March 27, 1882.	Febricula.	Five days.	Recovery.
Case VII.	April 2, 1882.	Febricula.	Four days.	Recovery.

In this series one important point should not be forgotten. The only members of the family who were exempted from illness were the two males, whose avocations kept them almost all day out of doors. This, with the other facts just mentioned, points suggestively toward some deleterious influence at home. The water used in the house was the Cochituate, and as sickness from its use was not noticed elsewhere, we cannot look to this as having an influence. Nor could I suspect the milk used, as other families were employing the same milkman without harm. Let me say, too, that the family where the sickness occurred is a respectable and industrious one, of neat and orderly habits, and not addicted to any of the common vices. They occupied a suite of rooms in a large and apparently modern building of good appearance. At my early visits in the family I did not notice any especial hygienic defect. There was not then observed any bad odor, and I had no suspicions as to the condition of the house. After the complications of gangrene and empyema arose, and the case of phlegmonous erysipelas followed, I was convinced that the drainage was defective. The Board of Health was notified, and courteously gave me the following entry from the books: "There is a defective drain where waste pipes enter the cellar. A joint is loose, bad odors escape. There are no traps whatever to the sinks in the house. There is no furnace. The soil pipes are not ventilated. Offensive odors from want of traps noticed."

A burning question in the pathology of to-day is, Is pneumonia an infectious disease, or is it a simple inflammation?

As is well known, Jürgensen, in the first edition of Ziemssen's Cyclopædia, expressed himself in favor of the infectious theory. In the second edition, not yet translated into English, we are aware that he has avowed himself a vigorous advocate of this view.

It is doubtless true that Jürgensen's theory has found many adherents in this country and abroad. Latterly much interest has been shown in a class of cases known as, "asthenic, adynamic, typhoid, contagious, epidemic, endemic," and the like. In this connection we recall various reports of what has been called "sewer-gas pneumonia." All are familiar with the epidemic mentioned in the Supplement to Ziemssen. This had its origin in the opening of the parish sewer located in the road nearly opposite a boys' school near London. The rooms facing the road were filled with foul-smelling sewer air. On the following morning a boy sleeping in one of these rooms was taken seriously ill with pneumonia. Others quickly followed, and one of the servants ultimately died. It is interesting to note that Sir William Jenner, whose son attended this school, predicted the attack of pneumonia as likely to follow the escape of sewer gas.

In the *American Journal for Medical Sciences* for January, 1876, Rodman describes most graphically a similar epidemic in a prison in Kentucky. In the course of a year one hundred and eighteen cases of pneumonia occurred, ninety-eight of which ran a peculiar course. This epidemic was plainly attributable to foul odors arising from hygienic defect. Ziemssen's Supplement also mentions Kühn's report of outbreaks in a jail in Hanover. Pneumonia here was also of a peculiar type. This important addition is made to his report: "There were also," he says, "numerous cases of an ill-defined febrile affection, the onset of which was preceded by pain in the head and back, and malaise. They ran a mild course with sudden defervescence about the tenth day, and were followed by a tedious convalescence." I was not aware of this report when I first made my conclusions, but they sound strikingly like the cases of febricula mentioned in my series.

Finally, in the absence of other known cause, is it not fair to infer from this combination of circumstances that sewer gas was the cause of, or at least an important modifying factor in, the case reported in this paper? Whether pneumonia is always an infectious disease is of course an open question. May not the conclusion in the Supplement to Ziemssen be, at least for the present, a safe working theory? "*Pneumonia is often simply an inflammatory disease, but it may depend on various miasmatic influences and then present decided variations in its course and symptoms.*"

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASE.

BY FREDERICK C. SHATTUCK, M. D.

INCISION OF THE PERICARDIUM.

SINCE the case of Rosenstein[1] three others have been reported. Partzevsky[2] communicated to the Moscow Physico-Medical Society the case of a man of twenty-three who, four years previously, had gone through an attack of right pleurisy with obliteration of the cavity, partial atelectasis of the right lung, chronic inflammation of its apex, and contraction of the right summit of the chest. He entered the hospital with the signs of left pleuritic and pericardial effusion of recent origin, and absorption soon began, progressing rather more rapidly in the pericardium than in the pleura, indeed, within six weeks all traces of pericarditis disappeared. In the seventh week, however, it was evident that the fluid was reaccumulating about the heart, although absorption was still progressing in the pleura. On the sixty-third day after admission the pleural effusion was gone, but the area of cardiac dullness extended from the right nipple to the left axillary line and upwards as far as the second rib; the cardiac region bulged outwards; the apex beat had disappeared,

[1] Vide JOURNAL, 1882, vol. cvi., p. 158.
[2] London Medical Record, February 15, 1883.

the heart sounds were almost inaudible, and the pulse could scarcely be felt; respiration 52; there were extreme cyanosis and general weakness; swallowing was almost impossible. Under these urgent circumstances the author decided to remove pressure on the heart by tapping, and after an exploratory puncture with a hypodermic syringe an aspirator needle was inserted in the fourth [left?] interspace, within two inches of the sternum, and about two and one half pounds of brownish, turbid, serous fluid were drawn off. This was immediately followed by great relief (pulse full, regular, 96; respiration 36; decrease of cyanosis; easier deglutition), which, however, lasted only three days. On the fourth day the patient had a chill and a morning temperature of 102.7° F., and on the sixth the pericardium was again greatly distended. The symptoms of incipient pulmonary œdema led to a second aspiration on the eleventh day, but only three ounces of pus were obtained. On the following day, the condition of the patient growing worse, an incision was made in the fourth interspace, and two drainage tubes were inserted, through which an enormous quantity of pus escaped. The pericardial cavity was washed out with a salicylic solution (one to three hundred), and Lister's dressing was applied. During the next ten or fifteen hours the patient felt much better, but a sleepless night had utterly broken his remaining strength, and he died in a state of collapse about thirty hours after the operation.

The autopsy showed that the pericardium, which contained three ounces of pus, was greatly thickened and covered with false membrane, that the right ventricle was hypertrophied, and the cardiac muscle fattily degenerated. Both pleural cavities were obliterated, and the lungs atelectatic and œdematous. The liver was pushed up to the fourth rib, and fixed there by adhesions to the diaphragm.

Of the author's conclusions we have space only for the fourth: "In cases of purulent pericarditis it is perfectly justifiable to try an early operation in order to prevent dilatation and fatty degeneration of the heart, which generally supervene here very rapidly."

The second case was reported by Dr. West[1] to the Royal Medical and Chirurgical Society. A boy, aged sixteen, had a large pericardial effusion. The symptoms became so urgent that paracentesis was performed. Pus was obtained. Three days later paracentesis was again performed, and subsequently the pericardium was laid freely open, evacuated, washed out, and a drainage tube inserted. The temperature never rose, and the boy recovered entirely in five weeks, the only feature of interest being an attack of general urticaria, which came on a week after the operation, and lasted three or four days. The following points of special clinical interest were emphasized: (1.) The absence of any special signs to indicate the nature of the effusion. There was no friction to be heard before the operation, or mill-wheel sound characteristic of hydropneumo-pericardium after the free incision. (2.) The place selected for puncture and incision was the fourth interspace immediately below the left nipple. (3.) Fourteen ounces were removed by the first tapping, two quarts by the free incision. (4.) A peculiar epigastric prominence noticed before paracentesis disappeared after operation. (5.) An attack of urticaria. (6.) The pulsus paradoxus, which was constant up to the time of the free incision, disappeared immediately after.

The discussion which followed the reading of the paper was an interesting one, but we can only notice the remarks of Mr. Hulke, who advised the very cautious use of the trocar or needle, and careful dissection down to the pericardium in cases of free incision. He had himself, after medical consultation, in a case which was believed to be one of pericardial effusion, once inserted a trocar and canula somewhat boldly, and the withdrawal of the trocar had been followed by a jet of blood, which gave him great anxiety, but, happily, relieved the patient. A subsequent post-mortem examination showed him that he had punctured the right ventricle, and that the case was one of universally adherent pericardium.

The third case was reported to the Pathological Society of London, also by Dr. West.[2] The patient was a boy of fourteen who, ten days after a severe fall, developed an abscess in the left shoulder, which was incised, and subsequently counter-opened. In addition to pyrexia there were cyanosis and dyspnœa with the signs of pneumonia of the left base. Some days later a few ounces of serum were removed from the left pleura. A second puncture a little later revealed no fresh fluid. The pericardium was felt to be full of fluid by the finger inserted into the side wound, and was incised, with the removal of twenty-four ounces of pus. The patient was relieved for the time, but the dyspnœa and cyanosis continued, and the patient subsequently died in the ninth week from the accident. The autopsy showed a large abscess in the left thigh, and inflammation of the left ankle-joint. There was extensive thickening of the mediastinal tissues, the arteries being deeply imbedded in it. The left pleura was divided by adhesions into three parts, each containing serous fluid. The pericardium was in great part obliterated except at the apex; there was no obstruction of any of the vessels. Dr. West drew attention to the fact that in this case incision had entirely relieved the pericardium, which was rapidly tending towards obliteration fourteen days after the operation, and that death appeared to be due rather to the other lesions present. Dr. West held that surgical interference with the pericardium is not more dangerous than, if, indeed, so dangerous as, that with the pleura or peritonæum.

[Of the four recorded cases in which the pericardium has been incised two were uncomplicated and recovered, two were complicated and died, though apparently in spite, rather than in consequence, of the operation. In West's case the cause of death was pyæmia. In Partzevsky's there would seem to be a possibility that the patient might have recovered if the operation had been done earlier. These facts justify the measure, and indicate that it is likely to become a generally recognized method of treatment. As far as we know the experiments of Dr. Rotch, of this city, which tend to show that the fifth *right* interspace near the sternum is the safest place for aspiration in pericardial effusion, have not yet been put to the crucial test in the living subject. Whether this be the place of election for tapping or not, it is obvious that a free incision into the pericardium should be made in the left side. — REP.]

AN ELASTIC RESPIRATOR AS A MEANS OF TREATMENT FOR EMPHYSEMA.[3]

The shortness of breath which characterizes this disease is largely due to the inability to expel enough air

[1] British Medical Journal, 1883, i., 814.

[2] Lancet, 1883, ii., 991.

[3] Féris, Bulletin Gén. de Therapeutique, 1883, vol. cv., p. 104.

from the chest to make room for a fresh supply, the elasticity of the lungs being lost, and the thorax becoming fixed in the position of full inspiration. The idea of aiding expiration by artificial means is no new one, but pneumatic cabinets and Waldenburg machines for compressing and rarefying air are not portable, a fact which greatly limits the real service these methods, and especially expiration into rarefied air, may be made to render. Impressed with the desirability of having at command some comparatively simple means for exerting a more constant expiratory force in emphysema, M. Féris conceived the ingenious plan of applying a sort of truss to the chest much like that in use for double inguinal hernia. A pad is fitted to the spine with a spring extending from either side across the axillæ to the front of the chest, where the springs terminate in pads like those of a common truss, but larger and less thick. The two anterior pads are fastened together by a strap, and further held in place by straps over the shoulders. The author asserts that the apparatus, when well constructed, can be worn under the clothes without betraying its presence. That it may fit the chest so accurately as neither to be uncomfortable or unsightly, and not to embarrass the respiration it should be made to order for each patient. The pressure should, moreover, be applied where the emphysema is most marked, though those parts are generally the infra-clavicular regions. The action of the apparatus as an aid to expiration is readily understood; of course in inspiration the force of the spring must be counteracted, but this is practically no drawback as in these cases the inspiratory forces are usually increased by exercise.

M. Féris says: "I have used the elastic respirator in thirteen cases of emphysema. From the moment that the apparatus is fitted respiration is established, and forthwith the patient exclaims that his oppression is gone. He can then walk, go up stairs, and sometimes even run, with less fatigue." A patient entered the hospital at Brest for advanced emphysema, and with the aid of a double inguinal truss, improvised temporarily as a respirator, went about the house with comparative comfort. He soon asked permission to go about the town, but the truss caused such an apparent deformity of his person that he did not venture to wear it in the street. He therefore went without it, but after going three hundred yards or so was so oppressed for breath that he was obliged to invoke the aid of a nurse to return. He then put on his chest truss, sallied forth, and remained seven hours.

Stethographic observations show that the respiratory movements are enlarged and diminished in frequency while the apparatus is worn. It is claimed, moreover, that the invention has also the following merits: —

After being worn for eight or ten days the prominence of the chest in the emphysematous regions disappears, and it becomes very difficult to determine by inspection alone the seat of the changes. Furthermore, asthmatic attacks are lessened in degree and frequency, a result not to be wondered at when it is remembered that inspiratory spasm is the characteristic of such attacks. Again, the tendency of emphysema to spread is checked, and it seems probable that the impediment to the pulmonary circulation resulting in engorgement of the right heart is diminished.

As for contra-indications, the author thinks that none really exist. A little time is needed for the patient to grow accustomed to the presence of his truss. The maximum benefits are to be looked for in subjects under middle life with emphysema of the upper lobes. Still the apparatus is worth a trial as a palliative in general emphysema, or in that form which is met with in old people whose costal cartilages are ossified. In one patient who had attacks of hæmoptysis before using the apparatus they were certainly not aggravated by it.

PULSATING EMPYEMA.[1]

The writer has collected twenty-seven cases of this rare and interesting condition, four of which have been under his own observation. In three of these four careful post-mortem examinations were made, and their results were so nearly identical that M. Comby is led to think the following physical condition necessary for the production of pulsating general empyema: the left lung, namely, must be thoroughly compressed and also adherent to the pericardium, in order that the cardiac movement may be transmitted through it to the fluid in the pleura. In ordinary cases of large effusion the lung is compressed toward its root, and the heart is forced independently toward the side opposite to the fluid, but in ordinary cases the fluid never pulsates; this can only occur when the pericardium and lung are adherent. The pulsation sometimes extends over a large area in the lower portions of the affected side, and is sometimes limited to a local swelling which has no constant position in the thorax. Cases are recorded in which the pus burrowed downwards and formed a pulsating tumor in the lumbar region.

With regard to diagnosis, the only affections which can well be mistaken for that under consideration are pulsating pneumonia, which is extremely rare, pulsating cancer of the lung, and aneurism of the aorta. As an aid which may be of service for the differential diagnosis in doubtful cases it may be mentioned that a murmur, so often heard over aneurisms, and not unknown over soft cancers, has never been observed over pulsating empyema. One would think there should be no great difficulties in the distinction between these diseases, and yet in several cases the abscess was allowed to open itself for fear that it might be an aneurism. One of these merits brief notice. A woman received a blow, and six months later began to complain of pain in the side; after a time a hemispherical tumor appeared at the left border of the sternum, between the third and fourth ribs, pulsating synchronously with the heart, and transmitting the heart sounds. An abscess was thought of, but aneurism being feared the patient was kept in bed for three years, the tumor growing all the time in size. The skin finally inflamed, and the pus began to discharge, but a fistulous opening persisted for a long time, and six years after the pains in the side came on the patient was sufficiently recovered to resume her occupation as a washerwoman.

The prognosis as regards recovery is very unfavorable. The existence of pulsation shows that the disease is of long standing, and that the left lung has consequently contracted such adhesions that it cannot be expanded. Little can then be hoped from incision and drainage unless, perhaps, generous resection of the ribs be also practiced. The few instances in which good results have been obtained seem to have been examples of circumscribed empyema near the heart and transmitting its pulsation. "Although the prognosis

[1] Les Pleurésies Pulsatiles (empyème pulsatile), Comby, Archives Gén. de Méd., 1883, November and December.

is fatal it is not the same for all cases; some remain long stationary, and tolerate their effusion and pulsation for several years, the right lung preserving its integrity, but if the right lung is diseased or the seat of tubercles the end comes in some months or weeks."

To sum up, pulsating pleural effusions occur only on the left side, are always purulent, indicate hopeless compression of the lung, and are incurable.

ANTISEPTIC INHALATIONS IN THE TREATMENT OF PHTHISIS.

English and German journals have of late years contained a number of articles advocating the more or less continuous inhalation of carbolic acid and other volatile antiseptics in phthisis, a method of treatment which is not unlikely to come more into vogue with the development of the doctrine of the bacillus tuberculosis. It is found that pure carbolic acid can be inhaled for hours from an oro-nasal respirator without causing irritation of the air-passages, and some observers, prominent among whom are Burney Yeo, Curschmann, and Fraentzel, are favorably impressed with the results. Dr. Hassall,[1] of London and San Remo, has published several articles which tend to show that the application of volatile antiseptics to the respiratory tract by means of respirators and atomizers is inefficient. One of the methods pursued in his investigations was to charge a respirator with a known quantity of the agent, allow it to be worn for a fixed time, and then determine by quantitative analysis the amount of loss of the antiseptic in the form of vapor. The loss after periods of one and two hours was found to be comparatively trifling, and the sputum raised after the respirator had been worn never had the least smell of carbolic acid. He found, however, that when the agent is used on a series of cotton screens suspended in a room at a temperature of about 70° F. it is almost entirely volatilized. Acting on these experiments he has constructed at San Remo an inhalation chamber with a cubic capacity of 1170 feet, one door and one window, no chimney or fire-place, but a register communicating with a small furnace. With the desire that this method of inhalation may be fairly tested Dr. Hassall will allow its use to medical men of all nationalities in San Remo, so that any of their patients may make use of it under the observation and guidance of their own attendant.

ENDEMIC HÆMOPTYSIS APPARENTLY DUE TO A PULMONARY PARASITE.

Dr. Manson,[2] of Amoy, China, read a very interesting paper on this subject to the Medical Society of London. He finds that the expectoration of blood, generally in small quantities and very frequently, and bloody mucus is a common affection in Formosa and Japan, and on examining the sputum from some of these cases under the microscope he discovered the constant presence of peculiar ova, one two hundredth to one five hundredth of an inch in diameter, and containing no trace of embryos. After cultivating the ova in water with proper precautions for four to six weeks he was rewarded by seeing in nearly every ovum the development of active ciliated embryos closely resembling those of Bilharzia and other distoms. Soon after this period the embryo succeeds in breaking through its investment, and rushes through the water, assuming various shapes, with its cilia in constant motion, apparently in eager search of its intermediary host. Through a fortunate train of circumstances, for the detail of which we have here no space, Dr. Manson obtained a specimen of the parent worm, which after having been some time in spirit measured half an inch in length by a sixth of an inch in breadth, and a third of an inch in thickness. It was sent to Dr. Cobbold, who pronounced it a new species, and named it, after the discoverer, Distoma Ringeri. It seems probable that the parasite is communicated from one person to another in some way by means of water, and the affection appears to be a counterpart of endemic hæmaturia. China, as far as is known, is free from the disease, which is a very chronic one. Dr. Manson thinks that the constant or repeated small bleedings cannot fail in certain cases to produce, in time, a state of intense anæmia, rendering the subjects of it very liable to attacks of dangerous forms of other diseases. Two patients were sent him from Formosa, and he kept them in his house for some time for purposes of study, treating them by inhalations of atomized solutions and infusions containing quassia, kousso, santonin, turpentine, and sulphurous acid. By these means one patient was apparently cured, but the other was not benefited.

NITRITE OF SODIUM IN ANGINA PECTORIS.

We now know that other nitrites besides that of amyl dilate the smaller arteries and lower the blood tension. It has been found that nitro-glycerine is a valuable remedy in angina pectoris, while Reichert and Weir Mitchell have used nitrite of potassium for epilepsy, and shown that it has effects which are almost identical with those of amyl. Dr. Hay [3] has used nitrite of sodium in one case of angina with marked good effect, complete relief following within two or three minutes after administration. In the same patient amyl gave only partial relief, and nitro-glycerine, though equally efficacious with the sodium compound, produced disagreeable throbbing in the head, which the latter did not. The effects of the sodium were also more lasting than those of the amyl. Of the pure drug one grain is probably as much as it is safe to give at first, but the pure drug is not easy to obtain. Dr. Hay found that a specimen obtained from a London manufacturing firm of the highest eminence did not contain more than thirty-three per cent. of the *nitrite*, the rest being *nitrate*. This fact should be borne in mind, and allowed for in case small doses prove useless. The drug is freely soluble in water. [It may be well to repeat a caution which has already appeared in print. In the last edition, namely, of Ringer's Therapeutics the dose of sodium nitrite is inferentially stated as *twenty* grains, an amount which might produce disastrous effects if the sample were pure. Drs. Ringer and Murrell [4] gave fifteen-grain doses of the impure drug to hospital out-patients, and reported the cases briefly, stating the disagreeable sensations produced in some patients. An outcry was made in the daily papers, and severe strictures were passed upon physicians experimenting on patients with drugs the properties of which are unknown. It was thought best to bring the matter to the notice of the government of the hospital, which formally exonerated Drs. Ringer and Murrell from all blame. — REP.]

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

STATED meeting, February 7th. The President, DR. FORDYCE BARKER, in the chair.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

The special order of the evening was the discussion of the paper of Dr. T. Gaillard Thomas, on the above subject, read before the Academy December 6, 1883.

The discussion was opened by a paper by the PRESIDENT which was read for him by DR. GASPAR GRISWOLD. He said that the more eminent the authority from which they emanated, and the more admirable the method of their expression, the more dangerous to the profession and the community were erroneous views like those of Dr. Thomas, and the more necessary was it to refute them. Some of the points on pathology had never before been advanced by any other author, as far as he was aware, and he thought the whole tone of the paper was misleading because it was so thoroughly saturated with the idea of septic infection. He had adopted the view that puerperal fever was puerperal septicæmia, and it mattered not whether it assumed the form of metritis, phlebitis, cellulitis, peritonitis, or lymphangitis, the essence of the disorder was a poison, which was absorbed into the blood through some solution of continuity. The tendency to this pathology, which was the result of studying the disease in hospitals, had been rapidly growing in the last few years, especially among the German authorities; but he (Dr. Barker) had seen no reason to change the views which he had expressed in his work on the Puerperal Diseases, and he could not but state his conviction that in private practice, where septic influences rarely prevailed, twenty cases of puerperal fever, which were due merely to local inflammation, occurred to any one that was the result of septicæmia. Dr. Thomas had contended that the lochial discharge was a poisonous fluid, liable to infect the system through abrasions of the genital tract, and the prophylactic measures which he recommended were based on this theory. In his own opinion, however, this was a complete mistake, and in epidemics of puerperal fever (which sometimes broke out in rural districts after a long period of immunity) the disease differed altogether from septicæmia in its origin, modes of attack, symptoms, and anatomical lesions. In hospitals, where the epidemics were so frequent and fatal, he believed it to be due to nosocomial malaria. Dr. Barker then gave an account of an epidemic which occurred in the best portions and among the higher classes of the city, in New York, in 1873. That Dr. Thomas's views as to the dangerous character of the lochia were founded wholly on theory was proved, he thought, by the following quotation from his paper: —

"In every case the offensive fluid, called lochia, poisons these freshly made, unprotected wounds, and yet what are the usual results? Recovery uniformly, I might say universally, unless some unusual occurrence manifests itself to prevent this happy consummation. Theorizing about the matter, one would suppose that the mortality resulting from such a state of things must be excessive.... And yet the facts are these: only about one or two in every one hundred parturient women ordinarily die, when properly cared for during labor, even in public hospitals."

If, in the language of Dr. Thomas, she who was about to bring forth must be treated as one about to go through the perils of a capital operation, and if in every case of confinement the same preparations and precautions were to be made, as the surgeon insisted on in cases of ovariotomy, it seemed to him that it was the imperative duty of the State to make child-bearing a penal offense, except in those with sufficient means to enable them to carry out all the elaborate measures required. In this connection Dr. Barker quoted a letter recently published in the *Medical Record*, in which the writer said that after reading the reports of some of the late meetings of the New York societies, at which the extreme difficulty of preventing puerperal septicæmia was set forth, he would respectfully suggest to the Academy of Medicine the propriety of appointing a committee to devise means for requiring the fair sex (and if necessary enforcing the measure by law) to wear over the genitals from the appearance of the catamenia to the menopause an antiseptic pad, which should never be removed except under proper antiseptic precautions, such as the use of the carbolic spray. In Dr. Barker's opinion, when septicæmia was present in puerperal fever, it was simply as the result of antecedent trouble; the disease as a rule being due to other causes. In private practice occult atmospheric influences were, no doubt, often responsible for it; while in hospitals, as had been said, the trouble was apt to originate in nosocomial malaria.

In speaking of antiseptic injections, he said that while they were sometimes of service, their use was liable to interfere with the cicatrization of lesions resulting from labor. As long ago as fifteen years since he had employed intra-uterine injections, as would be found on page 320 of his Puerperal Diseases. While refrigeration might also be useful in certain instances, his experience with the method, as a rule, had not been favorable, and he then related several cases treated under his care at Bellevue Hospital, in which serious pulmonary symptoms had been occasioned by it. On page 476 of his work he had stated his creed, and unless some new facts could be educed to convince him of the correctness of Dr. Thomas's views on puerperal fever he expected to die impenitent.

At the conclusion of the paper DR. BARKER made a few additional remarks, in which he said that nearly thirty years ago he had used vaginal injections, of Talanague's solution, for a week after labor, and later had used carbolic acid in place of it. This practice he had habitually followed until within the last three years. By some observations made by Mr. Thomas Keith, of Edinburgh, during the International Medical Congress in London, in 1881, he was induced to reduce the strength of the carbolic acid injections one half, and during the past two years he had given up their use altogether. He did this with the less reluctance because he believed it to be a fact that the strength of any carbolic acid solution that could be used was not sufficiently great to destroy deleterious micro-organisms, if any were present; and he had been abundantly satisfied with the result, since during the last two years neither himself or his colleague, Dr. A. A. Smith, had had a single case in which there had occurred the slightest interruption to perfect convalescence after parturition, or in which anything more than

the ordinary attendance was required, namely, one daily visit for nine days.

Dr. W. M. Chamberlain made some remarks in regard to the advantages of the tube which he had devised, and stated that he had anticipated one of the modifications of its construction which Dr. Thomas had suggested, namely, bringing the holes nearer the extremity.

Dr. H. T. Hanks spoke of the prevalence of puerperal fever in the country as well as the city, and gave some statistics of the disease in New York, from which it appeared that during 1883 262 patients had died from it, while during the past five years there had been 1005 deaths. From his own experience it was clear to him that no hypothesis could satisfactorily explain the phenomena met with in it except septicæmia, and, consequently, he agreed in the main with Dr. Thomas's plan of prophylaxis and treatment. The ante-partum injections, however, he thought unnecessary, and the use of ergot three times a day for a week seemed to him unjustifiable and harmful, except in cases where the uterus did not contract well. After more remarks on the primary operation for lacerated perinæum, he spoke of the treatment of puerperal septicæmia, and begged to add two suggestions: The first was in reference to the use of aromatic spirits of ammonia, which he advised to be given in half-teaspoonful doses every two hours, and the second was, that a bed-pan should be used when making intra-uterine injections, instead of moving the patient to the edge of the bed. He had devised one of block tin, upon which the patient could lie with perfect comfort, and he now exhibited this to the Academy. In conclusion, he said there were four assistants upon which he relied in every case of confinement which he was called upon to attend, and these were: Pure air, absolute quiet, judicious diet, and appropriate antiseptic precautions.

Dr. W. T. Lusk expressed the opinion that puerperal fever and surgical fever were absolutely identical, and that certain apparent differences were due simply to the anatomical differences between a clean cut wound and the condition of the genital tract after parturition, in regard to which it was necessary to take into consideration especially the capacity for rapid absorption and the nearness of the parts to the peritonæum. A great deal of difficulty and difference of opinion had originated, he thought, in not recognizing the distinction between putrid intoxication and septicæmia. This difference depended on the presence or non-presence in a decomposing fluid of special micro-organisms; and the treatment that was appropriate for one condition was not at all adapted to the other. The rod bacteria were not absorbed in the human subject, and the putridity of any discharge was not the source of septicæmia proper. It was only the warning that round bacteria, which were capable of being readily absorbed, multiplied, and distributed to various parts of the system, were likely to be generated.

In regard to the matter of prophylaxis he thought that too much of a burden in the way of detail should not be placed upon the practitioner, and, for one thing, he did not believe that the antiseptic washing of the walls and furniture would be of any service, as he had done this faithfully in the lying-in wards of Bellevue Hospital, and it had never had the slightest effect. If in any house, however, in which a woman was to be confined, there had been a case of scarlet fever, diphtheria, or other infectious disease, he would advise that the room should be fumigated with sulphurous acid, if this had not already been done. He would also advise that patients should never be confined in rooms adjoining water-closets, as the puerperal woman was peculiarly susceptible to sewer-gas poisoning.

After an ordinary labor there was not likely to be primary decomposition in the cavity of the uterus, since the air was excluded from it. In the vagina, however, where there were heat, moisture, and air, the conditions were somewhat different, but if vaginal injections were made as soon as any bad symptoms appeared, all difficulty would be avoided. In labors in which it was necessary to introduce the hand or instruments into the uterus, those conditions were left which would be likely to result in putrid intoxication, and in every such case it was the duty of the accoucheur to thoroughly wash out the uterus at the time of the labor. In any case of puerperal fever where there was not a "puddle" in the uterus, there was not the slightest use in washing it out (though perhaps one injection might be made by way of precaution), as the septicæmia from which the patient was suffering was entirely beyond the reach of any such means of treatment as this. When last summer he had visited a number of the principal lying-in hospitals of Europe, he had found that it was universally the practice to wash out the uterus only in cases where air had been admitted to its cavity during labor. In Vienna they now used a suppository of iodoform with gum tragacanth, and while, up to a recent period, the mortality had been five or six per cent., during the last year there was only an average of one death in two hundred confinements. In Prague (where, however, the iodoform suppositories were not used) there had been 1100 cases of confinement without a single death, but it was only since the indiscriminate use of injections had been given up that these good results had been obtained. They were now never resorted to except where well-defined indications were present.

Dr. P. F. Mundé related his experience with the disease, and said that while, as a rule, puerperal fever and puerperal septicæmia were undoubtedly the same thing, there were certain cases in which he agreed with Dr. Barker, that sepsis was not the prime cause. In speaking of the treatment, he dwelt upon the dangers connected with the use of the intra-uterine tube, and said he agreed with Dr. Lusk, that it should only be employed to meet certain well-defined indications. Even then the injections should be discontinued at as early a period as possible.

The Chair now asked Dr. Thomas to close the discussion. In commencing his remarks he spoke of a murder trial at which he had been present when a lad, in which the counsel for the prisoner, when called upon to speak after the prosecuting attorney, simply said, "May it please your honor, the case is closed — I rest it here. The gentleman on the other side has made so able a speech in favor of my client that I rely upon it for his acquittal," and the prisoner was acquitted. Dr. Thomas said that he felt very much in this way in regard to Dr. Barker's paper; but as discussions such as this could not fail to do good, he thought it would be well to say a few words in self-defense. After mentioning his regret that the President had seen fit to use against him a two-edged sword like ridicule, which was, however, the poorest of arguments, and which only indicated the weakness of his position, he said that Dr. Barker's attack called for no rebuttal

and demanded no argument on his part, as he was perfectly willing to stand by the position of his paper of December 6th, in which he had said all that he had to say on the subject under discussion. There were, however, one or two points upon which he felt it necessary to touch in order to avoid misrepresentation.

Dr. Barker appeared to object to the fact that in his pathology he had not stuck closely to the dicta of the text-books, and hugged to his soul the tenets of a bygone time, as he himself had done; but if he had had no opinions of his own, founded upon thirty years' practice in a large metropolis and experience in great hospitals, he would not have appeared before the Academy at all. In accordance with the recent views of pathologists on this subject, however, it was his antagonist's opinions that were effete, and not his own that were jejune. As far as he could gather anything certain from Dr. Barker's discursive paper, the pivotal idea of his attack seemed based upon the belief that he (Dr. Thomas) regarded the lochial discharge as a poisonous fluid, which, by absorption by abrasions in the genital tract, gave rise to puerperal septicæmia. Such an absurd idea had never entered his mind. What he did state was, that the lochial discharge was a material ready to take on those alterations which were effected by micro-organisms of bad character, and which, changing its nature, rendered it poisonous to the abraded tissues. He believed that it would be found that the pathology which he had offered in his paper was merely abreast with the views of the advanced pathologists of Germany, France, and Great Britain. As to the pathology of his adversary, Dr. John Thorburne, of Manchester, England, very justly expressed concerning it, he thought, the accepted view of the profession, when, in a foot-note to an article upon Metria, in the *British Medical Journal* of August 11, 1883, he said: "It would be inexcusable not to make some reference to the very able papers of Dr. Napier in the *Obstetrical Journal* for 1880, on Puerperal Fever. He, along with Fordyce Barker, defends the old position of a specific puerperal fever *sui generis*. . . . I can only say that his invaluable collection of facts produces in me an opinion diametrically opposed to his own."

As to the want of thoroughness and sketchiness of detail with reference to his description of symptoms with which his critic had upbraided him, Dr. Thomas remarked that he had intentionally assumed this style, as his paper was distinctly announced to be one upon The Prevention and Treatment of Puerperal Septicæmia, and upon nothing else. The subject of that paper was the only legitimate one before the Academy at this time, and he hoped that those who had entered into the discussion to-night would pardon him for saying that we had heard a great deal in the way of repetition as to pathology, a great deal about tubes and the number of holes which should be made in them, and diverse opinions as to whether or not a suppository of idioform should be put into the vagina, and small doses of ergot given for a week or so post partum; but these were non-essentials, and hardly worth the valuable time which had been given to them, when so much of greater importance remained to be considered. The crucial questions which were before the Academy to-night were these: (1.) Are we to look upon puerperal septicæmia as a poison due to the development of micro-organisms, and are we by every means in our power to guard against the contact of these with the genitals of the puerperal woman? and, (2.) When the disorder is developed, is it best for us to keep our patient semi-narcotized and quinineized while the distended abdomen is covered with stupes of turpentine or poultices, and then await the result, as has been formerly done, or are we to seek to destroy the septic germ which has invaded the genital tract by means of local applications? These were the great questions. The other points were not essential.

Dr. Thomas then went rapidly over the suggestions which he gave in his paper for the management of ordinary confinement cases. In regard to the first, as to cleansing the lying-in chamber and applying antiseptic solutions to its walls and floors before labor set in, this seemed to appear to some like one of the labors of Hercules, but there was really no difficulty about the matter. He then described how simply it might be accomplished, and went on to say that although, as Dr. Lusk had seemed to find, it might not be of much benefit, he had never seen it do any harm, and until he did so he should feel that it was safe to resort to it. But at the same time he did not regard this cleansing of the chamber by any means essential. If, however, he needed any defense for having pressed the claims of cleanliness in this regard he hoped it would be found that he who offered rules for a system must aim high, and not low; that, aim as high as he might, many would fall below the standard, and that if a low level were assumed no one would go above it and take a higher. Dr. Thomas dwelt for a short time on his second and third suggestions for prevention, which are as follows: (2.) "The nurse and physician should take care that all their clothing, both under and upper, be clean and free from exposure to the effluvia of any septic affection. Should either of them have been exposed within a fortnight to the effluvia of such affections as scarlet fever, typhus, erysipelas, septicæmia, or the like, they should change every article of clothing, and bathe the entire body, especially the hair and beard, with a reliable antiseptic solution. That which I prefer for this purpose is a saturated solution of boracic acid." (3.) "As labor sets in the nurse, having thoroughly washed her hands, cleansed her nails with a stiff nail-brush, and soaked them in antiseptic fluid, should administer to the patient a warm vaginal injection of antiseptic character, bathe the vulva and surrounding parts freely with the same, repeat this every four hours during labor, and keep a napkin, wrung out of the warm antiseptic fluid, over the genital organs until the birth of the child." His fourth suggestion, he said, merely related to cleanliness of the hands on the part of doctor and nurse. And no one, he thought, would quarrel with the fifth, which merely required the physician to attend intelligently and faithfully to the performance of the third stage of labor, and the examination for and closure of wounds about the vagina and ostium vaginæ. In regard to the seventh suggestion, the use of vaginal injections every eight hours, beginning eight hours after delivery, he said that the arguments which had been brought up against this practice since he had read his paper had had great weight with him, and that he had to confess that he felt less firm in his convictions upon this point than he did. In the future, therefore, he would examine the question carefully before he determined to adhere to his plan. The rest of the rules would be so certainly agreed in that he could not question the concurrence of all, even of the eminent authority, the President of the Academy, who regarded his efforts as

so hurtful to progress and so dangerous to the community.

Passing to the means which he had suggested as to treatment, Dr. Thomas stated that with reference to his present views upon the use of cutaneous refrigeration for the controlling of high temperature, however produced, and occurring in the course of whatever disease, he could only say, after a very extensive experience, that were the laws of the country to prohibit a resort to this method he would be unwilling to continue the practice of his profession, for then he could not do so without relinquishing what he sincerely believed to be one of the most valuable therapeutic resources at the disposal of the physician. In regard to intra-uterine injections, he said that if he had expressed himself in such a way as to allow it to appear that he resorted to them with very little provocation, and upon all occasions when hyper-pyrexia supervened after childbirth, no impression could be more erroneous. No one could have striven more than he had done to keep within proper bounds the indiscriminate use of this valuable but dangerous resource. He hoped that Dr. Barker would here allow him to offer a most full and sincere apology for not having accorded to him in his paper the credit which was his due in connection with the introduction of intra-uterine injections into obstetric practice, as the omission was due to ignorance of the facts which he had stated, and not to any intentional neglect.

He had not been surprised, he went on to say, to notice, among other criticisms of the preventive measures which he had suggested, a tendency on the part of some to ignore the necessity for them, especially in private practice, and he had come here prepared to use some statistics which would invalidate this position. He would not use these, however, but employ in their stead some which had been offered by the speakers of this evening. Dr. Hanks declared that more than 250 women died from puerperal septicæmia in this city last year; that was 250 to 1,000,000 inhabitants. The United States probably contained, in round numbers, 40,000,000 inhabitants, which would give us 10,000 deaths in one year, and in twenty years, which was about the average child-bearing time of women, 200,000 deaths. Surely this looked as if something ought to be done to lessen the mortality of this disease. That the plan which he had suggested would accomplish this result he thought was proved by the statements of Dr. Lusk, who had just told them of the remarkable results obtained in Prague since the adoption of a similar plan. Some might object that these were the statistics of hospitals, and that the disease was certainly rare in private practice. Such was not the case, however, for in the two months that had elapsed since he had read his paper he had been called to no less than five cases of puerperal septicæmia, all of which were of the most desperate character. Dr. Thomas mentioned the different practitioners with whom he had seen these cases in order to show, as he said, that instances of the disease occurred even under the most favorable circumstances as to social surroundings and medical care, and then concluded his remarks in the following words: "I feel very sure, gentlemen, that you will give full credence to two statements which I make in bidding you good night. First, that I have no wish to be dogmatic and uncompromising in reference to the rules which I have suggested for the prevention and treatment of puerperal septicæmia. Second, that if venom has seemed to flow from my tongue it has not reached it from my heart, which has been entirely free from it, and that if I have seemed to strike too trenchant blows at the honored head of our President I have struck purely in self-defense at one for whom I would yield to no man in respect, admiration, and affectionate regard."

ESSEX NORTH DISTRICT MEDICAL SOCIETY

QUARTERLY MEETING, WEDNESDAY, JANUARY 23, 1884.

REPORTED BY E. P. HURD, M. D., CORRESPONDING SECRETARY.

A QUARTERLY meeting of the Essex North District Medical Society was held in Lawrence, January 23d ult., at the house of Dr. C. N. Chamberlain, President.

An interesting paper was read by DR. LESLIE, of Amesbury, on Ovarian Pain. Several illustrative cases were reported by the reader.

DR. HOWE, of Lawrence, read a paper on

ADDISON'S DISEASE,

reporting one case.

A year and a half ago Dr. Howe was called to attend A. B., female, unmarried, aged twenty-four years. Of naturally fair complexion, she suddenly became bronzed; face and neck, hands, arms, and thighs of a dark-brown color; bronzing less marked over chest and back; dark areola around nipple. The discoloration even invaded the gums and mucous membranes. Patient rapidly lost strength, and in one month died in collapse. No autopsy. The reader gave a brief history of Addison's disease, regarding it as a chronic inflammation of the supra-renal capsules, terminating in caseous degeneration of the inflammatory products and of the elements of the tissues themselves. The cause of the bronzing is unknown.

DR. HOSMER, of Watertown, President of the State Society, who was present by invitation, gave an oral report of three cases which had come under his observation. In one of these cases, a patient of fifty-three, phthisical, and ill for some months, the autopsy disclosed supra-renal capsules enlarged and transformed to cysts containing liquid. A prominent symptom in this case was palpitations, coming on without any known cause, due probably to some fault of innervation.

In all of Dr. Hosmer's cases excessive prostration with irregular action of the heart, headache, etc., accompanied the tanned appearance of the skin, characteristic of the affection. Patients of naturally fair complexion become so bronzed as to resemble mulattoes.

DR. HOWE, of Newburyport, reported two similar cases occurring in his own practice, in which the bronzing was accompanied by anæmia and debility. In one case where the patient died suddenly an autopsy was held which revealed atrophic degeneration of the capsules. All treatment seems unavailing in these cases.

DR. G. M. GARLAND, of Boston, gave an interesting discourse on

THE TREATMENT OF GLEET AND GONORRHŒAL STRICTURES BY OTIS'S METHOD,

illustrating his remarks by citing results from his own private and hospital practice. Formerly it was taught that strictures were the consequence of prolonged gon-

orrhœal irritation. Otis, of New York, has revolutionized the theory of the location of strictures. There are certain places in the urethra with physiological narrowing which back up the secretion, so causing irritation, inflammation, and granulation of the mucous membrane and inflammatory submucous thickening and stricture. The first of these is from one half to one inch from the meatus. A case having a slight stricture here (24 French, while the urethra behind was 34) was operated on three weeks ago, and the gleet is now entirely well.

Otis shows that the ratio between the size of the urethra and circumference of the flaccid penis is physiologically constant. A penis with a circumference of three inches should admit a sound of No. 30 French. One of four inches a No. 40 French. No. 38 French is frequently used, after cutting slight strictures, with no pain at all. Any stiff instrument below 15 in size is dangerous to use in these cases, and a soft catheter should be employed rather than a stiff one.

In searching for strictures a large sound stretches them, and gives no satisfactory evidence. Hence a full set of acorn bulbs or one of Otis's urethrometers should be used, which has a gauge for the size of its bulb from 12 French upwards. Pass this instrument deep into the urethra and distend till it causes discomfort, then begin to draw back easily without force till it brings up at a stricture. Now read off its distance from the meatus, and relax the bulb till it passes through, noting the size of the stricture by the reading of the gauge. Then distend again, and repeat as before. In one case five strictures were distinctly located between the ligament and the meatus. There had been here a gleet of twenty years' standing. These strictures vary from 19 to 28 or even 35 French. The next step is to cut them. Otis's method can limit the cutting with a scientific exactness. All other methods trust more to luck.

In divulsion there is no control or knowledge of the amount of injury. The urethra is made tense by Otis instrument, and cuts of exact locality, length, and depth are made. The instrument is removed and bulbs passed, and if any trace of stricture remains the operation is repeated.

Otis, now, never does the operation in the membranous portion of the urethra. Here slow, careful stretching is alone allowable.

One case of Dr. Garland's had penile strictures allowing only a No. 9 bulb. These were cut up to No. 34, and then the membranous portion was still closed and it was impossible to get into the bladder. But after healing from the operation, a No. 12 was passed, and by two sittings this was increased to No. 18 French, and the patient was back at work.

If membranous strictures cannot be cured by slow dilatation, the only resort is perineal section. The preparation for the operation should include dosing with liquor potassæ for a day before, and the urine should be kept alkaline through the healing stage.

As a rule give quinine; keep the bowels empty. Ether is advisable for deeper strictures, but not for those at meatus.

As a rule, do not operate till the acute inflammation has subsided, though this need not deter in urgent cases. Cut on the upper surface of the urethra in deep strictures, but below in those near the meatus. Let the patient alone for forty-eight hours, without catheter, as urine will be passed without harm.

An attendant ought to be by for twenty-four hours, as there is danger of secondary hæmorrhage, especially if an erection occurs during sleep. Especially is this to be feared in about eight or ten hours after the operation. In forty-eight hours pass the catheter every other day, and distend gradually with the sound, until by the eighth or ninth day the passage should be fully distended, as it heals quickly about this time and a serious contraction may otherwise occur. Generally keep the patient in bed a week. If the cuts open the urethra to No. 36 French, it would be expected to heal, allowing passage of No. 33.

While the operation is simple it still necessitates great care. The danger from hæmorrhage is slight, as it is always easily controlled. Some patients lost only three or four drops of blood. A temperature above 100° F. is rare.

Dr. Garland's oral discourse was followed by a brief discussion, in which several of the members related their unsatisfactory experience in the treatment of urethral strictures with the older methods of gradual dilatation and divulsion.

The meeting ended with a sumptuous entertainment provided by Dr. Chamberlain.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICO-LEGAL SOCIETY.

W. H. TAYLOR, M. D., SECRETARY.

NEW MEMBERS. PUBLICATIONS, COMMITTEES, ETC.

FEBRUARY 6, 1884. The meeting was called to order at 12.15 P. M., by President PRESBREY. Present, twenty-one members. Records of the last meeting were read and approved.

The nomination of Medical Examiner J. M. Crocker, of Provincetown, as a regular member of this Society, was referred to the Executive Committee, with instructions to report at this meeting.

The PRESIDENT announced that Clark Bell, Esq., President of the New York Medico-Legal Society, had made certain propositions to the Society regarding publication of the transactions, and representation in the *New York Medico-Legal Journal.*

On motion of Medical Examiner PINKHAM, the papers were referred, without being read, to the Standing Committee, with power to act in the matter.

The Executive Committee having reported favorably upon the nomination of Medical Examiner Crocker, he was unanimously elected to regular membership.

Theodore M. Osborn, Esq., of Peabody, was unanimously elected an associate member of the Society.

Corresponding Secretary PINKHAM made a partial report of the work of medical examiners, and gave his views upon methods of making returns, which elicited some discussion.

Medical Examiner TOWER read an obituary notice of Medical Examiner W. M. Parker, of Milford, at the time of his death a regular member of this Society.

Upon motion of Medical Examiner TOWER, voted to note the fact of such reading upon the records of the Society.

Voted, upon motion of Medical Examiner DRAPER, that the Standing Committee be authorized to select cases from the files of the Society for publication in *The Boston Medical and Surgical Journal.*

Upon motion of Medical Examiner TOWER, voted

to appoint a committee of three to consider the law of medical examiners as to its defects and needs, with a view to changes therein, the committee to report at the next meeting of the Society. The President appointed Medical Examiners Tower, Draper, and Hosmer such committee.

Medical Examiner Fish read a valuable paper on External Appearances of Pistol-Shot Wounds, which was received with applause by the Society, and led to considerable discussion.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

February 11, 1884, the President, Dr. Charles D. Homans, in the chair.

Dr. F. C. Shattuck exhibited a patient with

MULTIPLE SARCOMA OF THE SKIN,

under treatment by hypodermic injections of Fowler's solution, from four to six minims once daily.

Dr. Francis Minot read a paper on

THE TREATMENT OF ACUTE PNEUMONIA,

which may be found on page 169 of this number of the Journal.

Dr. C. E. Stedman spoke of the untrustworthiness of statistics of the disease. Grouping a number of cases, subjected to the same treatment, but necessarily omitting to note their severity, is of no value. Trousseau's statistics omitted the cases that would have recovered at any rate, and gave him a mortality of eighteen per cent. Grisolle's, also leaving out light cases, sixteen per cent. Wurmb and Caspar twelve and fifty-five hundredths per cent., treated with bleeding and drugs. The homœopathic hospital in Leopoldstadt ten and a half per cent. The readings of papers like Dr. Minot's is of far more value to students than the study of statistics.

The speaker referred to the importance of rest. He mentioned a patient with single pneumonia doing well, who on the seventh day was moved on to a lounge by officious friends, anxious to make the bed, and who died three days later in consequence, as he believed, of being moved about. He was pleased to hear the jacket-poultice disapproved of. It is dirty, and it is no light thing for a patient to raise two or three pounds of mush forty times a minute. Flannels wrung out in warm water will amuse busy attendants as well. He supposes every one cautions patients against talking. It is of the greatest importance. Examinations of the chest are of course necessary until the diagnosis is made. After that they should be as seldom as possible. Dr. Stedman spoke of the striking effect of a change of position. He once had a lady propped up in bed, intending to bleed her for an access of dyspnœa, but getting her up relieved her so much that he left her unbled. She remained propped up all night, and finally recovered. He thinks that the pulse is the indicator for stimulants. A patient with a pulse of 115 or lower always does well unless there is some fresh warning.

Dr. J. B. Ayer had rarely known the discomfort of a jacket-poultice to be complained of. If the front and back are separate the back need not be often changed.

Dr. Minot, in answer to the last speaker, said that he never gave quinine as a sedative.

Dr. H. W. Williams asked the reader what is the incubation period of pneumonia.

Dr. Minot answered that it is probably a short one. It is hard to settle the question.

Dr. Williams said that homœopathic statistics had been referred to. When he was in Vienna he had been to the homœopathic hospital to see if anything of value could be picked up, and had seen numbers of cases called pneumonia, but not having so far as he could see symptoms warranting the name. On asking the reason for the diagnosis he was told by an attending physician that these patients would have pneumonia if it were not broken up.

Dr. Minot, to a question of Dr. H. C. Haven's, said that he thought a nursing child with the disease would continue to nurse. He, however, rarely sees the disease in children under a year, though often between one and three years. Bailly and Legrange show that many cases of atelectasis pass for pneumonia, giving rise to another variety of statistics. When a student at Paris in 1845–1847 tartar emetic was given at the *Enfants Malades*. Many died.

Dr. R. H. Fitz asked if there is evidence of contagion.

Dr. Minot answered no. We often have more than one case in one house. The disease is not communicated to other patients in hospital wards, so far as he knew.

Dr. C. E. Stedman said that during the late war pneumonio was supposed to be contagious on the receiving ship Ohio. She was greatly crowded in cold wet weather, and there was excessive mortality. He was himself on medical duty at the yard, and knew the opinion of the medical officers of the ship.

Dr. F. C. Shattuck alluded to the report of an apparently similar outbreak which took place on some English war vessels in the Mediterranean. A very recent number of the *Zeitschrift für klinische Médicine* contains an article by Mendelssohn on the infectious nature of pneumonia. This writer has made a pretty full collection of the literature bearing practically on the infectiousness and contagiousness of this disease, and has also availed himself of the discovery of an organism peculiar to it by Klebs, Koch, Friedländer, Leyden, and others. The latter has found the parasite in the material which he withdrew from the solidified lung of a living patient by a hypodermic syringe. Mendelssohn's article is not fair in some respects. He speaks, for instance, of some very interesting prison epidemics, notably those reported by Rodman and Kühn, as if they were of pneumonia pure and simple. Any one who takes the trouble to consult the original articles will see that the cases differed widely from the common lung fever, which, as Dr. Minot remarks, has always until of late been classed among the local inflammations. It is true that in these prison epidemics there was pneumonia, but there were also albuminuria, swelling of the spleen, pericarditis, and other indications of septic infection in a very large proportion of the cases. There seems to be no reasonable doubt that over-crowding and defective sanitation played a very important rôle in these epidemics.

Dr. F. Gordon Morrill referred to experiments when the sputa was injected into each of seventeen rabbits. The five rabbits who survived five days were then killed, and found to have hepatized lungs.

Dr. F. H. Williams spoke of cases in which the

peculiar ratio of pulse to respiration does not occur. He had seen a patient whose respirations are commonly ten or twelve, but were increased to sixteen or eighteen during pneumonia, the pulse becoming one hundred and twenty to one hundred and thirty.

DR. H. C. HAVEN showed a specimen from a case of

CEPHALHÆMATOMA.

DR. FITZ mentioned the condition of the specimen as it appeared soon after the death of the infant. The unusually small quantity of blood present, considering the area of detachment, was specially noticeable, and permitted a relatively close contact between membrane and bone. Osseous scales were to be found in the detached periosteum as well as the bony ring at the attached margin, both giving evidence of the rapidity of bone growth at this early period of life.

The sudden disappearance of the larger part of the contents of these tumors was, to the best of his recollection, a very unusual event in their history. Although a discoloration of the skin might well result from the rapid absorption of large quantities of blood-coloring matter, he thought it unlikely that such absorption should give rise to disturbance of nutrition. As a rule weeks and months elapse before the contents of these tumors are removed without operative interference, and most physicians would be pleased to see a more rapid disappearance. A septic poisoning as a result of opening the sac has often arisen, but he was unaware of any instance of injurious effects from the absorption of the contents of a cephalhæmatoma which had not been tampered with.

The usual and most satisfactory explanation of the origin of these tumors was the mechanical theory. According to this the act of expulsion of the fœtus caused a partial detachment of the dura, and the hæmorrhage from the ruptured vessels took place after the birth of the child. This view was supported by the absence of any evidence of pathological causes acting during intra-uterine life, and was not satisfactorily opposed by the occurrence of the tumor in cases of rapid delivery or of breech-presentation.

Recent Literature.

Elements of Human Physiology. By HENRY POWER, M. B. Lond., F. R. C. S. Illustrated with Forty-Seven Engravings. Philadelphia: Henry C. Lea's Son & Co. 1884. Small 8vo. 389 pages.

This handy little book is a companion volume to Klein's Histology, which was recently noticed in this journal. As other complementary volumes treat of Clinical Chemistry, Physical Physiology, and Comparative Anatomy and Physiology, much that the student requires is omitted in the volume before us. At the same time not a little is apparently retained which ought to have fuller treatment, and perhaps gets it elsewhere. The result is a convenient and pleasant aid to the intelligent pupil cramming for an examination. The defects of the book are those common to all small physiologies which are not really elementary.

Power's Physiology may also be recommended as an agreeable syllabus to a good course of lectures which should correct some of the views presented that are inexact or only historically interesting. It suffices here to note in this connection: the ozone theory of the blood-gases (page 22), the influence of a change of one per cent. in the oxygen of the air (page 69), and the antizymotic properties of potassium sulpho-cyanide (page 103). The account of the localization of brain function (pages 260–263) will mislead the trusting reader.

The printing is excellently done, and there is a pretty full index. In this we miss "Sleep" (page 267), and note that curare is indexed as "Woorara," although the former name is preferred in the text. The chief misprint which has attracted attention is "quarrversuch" (page 233). Here, too, the suggestion may perhaps be permitted that it is high time to substitute "katelectrotonus" for the carelessly formed "cathelectrotonus."

In the account of muscular contraction (page 194) our author remarks: "There is no short term in English to designate the sudden, short, and transient shortening which is termed by the French a *sécousse*, or shock, and by the Germans a *zuckung*, or convulsion." Amory's translation of Küss's Physiology has "jerk" for this phenomenon, but the word is not altogether a happy one. Some years ago Dr. C. S. Minot, in his Experiments on Tetanus,[1] proposed and used "twitch" as an exact equivalent of "zuckung." This has always seemed to us a most felicitous suggestion and worthy of general adoption.

In the chapter on Food we are informed (page 86) that alcohol "in small quantities and in a diluted condition probably does little or no harm, but taken in excess it causes exhaustion and leads to poverty, and vice, and misery." This, as well as the remark on masturbation (page 328), does not, we submit, belong to the proper Elements of Human Physiology.

In a word, the book before us is a good one, — almost a very good one. Whoever reads it with care will learn *multa* if not *multum*.

The Australasian Medical Directory and Hand-Book. Edited and Compiled by LUDWIG BRUCK. First Year of Publication. Sydney: Published at Australasian Medical Gazette Office. London: Baillière, Tindall & Cox. 1883.

This Directory and Hand-Book furnishes a great deal of information concerning the field it professes to cover. Besides a list of nearly 1700 legally qualified medical practitioners, resident in the colonies, their names and addresses, qualifications, past and present appointments, it contains a general gazetteer of 1000 post towns, together with all particulars that may be useful to a medical man, combined with a local directory of all resident physicians, surgeons, veterinary surgeons, and dentists, as well as a list of benevolent and similar institutions. It also contains an abstract of all the principal laws affecting the medical profession throughout Australasia, an intercolonial official medical directory, a list of medical and other scientific societies, the regulations and by-laws of colonial universities, a list of coroners, a recognized scale of medical and surgical fees, a short history of 130 universities in all parts of the world, a list of upwards of 200 periodicals devoted to medicine, surgery, and allied sciences that are published in the English language throughout the world, an obituary, and many other features, the mere enumeration of which would fill a column. We understand the book is not only full but accurate.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 21, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 Park Street, Boston, Mass.

"TRANCE" AS A SYMPTOM OF HYSTERIA.

One of the most interesting cases of continued lethargy or "trance" yet reported is that which came recently under the observation of Professor Gairdner, of Glasgow.[1] The case, briefly stated, was that of a woman who, after childbirth, showed a hysterical tendency, which culminated after eleven weeks in a lethargic sleep, which became gradually so profound that the most powerful external stimuli failed to produce the least sign of consciousness. The limbs lay flaccid without sign of cataleptic rigidity, the evacuations were passed in bed, the flesh wasted away, and the patient was preserved from inanition only by continued feeding with the stomach tube. This condition lasted nearly three months, and after recovery the patient professed entire unconsciousness of the events occurring during her protracted sleep.

The report of the case and the comments of Professor Gairdner upon it well illustrate the encroachment of science upon the domain of popular superstition. In earlier times hysterical and epileptic convulsions were considered due to the possession of the patient by devils, while their cessation was generally attributed to miraculous interposition. If such every-day phenomena as these have been in times past referred to supernatural agencies, who can wonder that the word "trance" is even now surrounded with uncanny associations, and that the popular mind, ever on the alert for the marvelous, should still cling to the idea that nature has in this case at least suspended her laws, and that spirits from some less tangible world have taken possession of the sleeper. The tendency of scientific research is to show that miracles do not exist, and the observer, trained by such research, is led to attribute the phenomena not yet understood to some law or laws not yet discovered, and the non-scientific world seems to be tending gradually towards the adoption of the same view.

Not many centuries ago multitudes of insane and epileptic patients flocked to the little town of Gheel, in Belgium, to be treated by the priests, whose exorcisms and prayers had gained a wide reputation for their potency over demoniacal possession. The priest has now retired in favor of the physician, and the town has become one vast lunatic asylum, with its headquarters in a new brick building with modern improvements, while in the comparatively deserted old chapel are still shown the chains once used to confine the restless "possessed" while awaiting their turn at the altar.

Convulsions, paralyses, and other symptoms occurring in epilepsy, insanity, and other *comparatively* tangible forms of disease, have been now long recognized as arising from definite disturbance, organic or functional, in the nervous system; and however obscure and difficult of analysis that disturbance may be, no intelligent medical man would throw doubt upon its existence. With hysteria the advance has been slower, and until a comparatively recent date the medical world has contented itself with substituting for the objective devil of the ancients a subjective devil, called variously "imagination" and "desire to be interesting." These and similar terms, implying either self-deception or the deception of others on the part of the patients, have long been supposed not only to represent the state of mind of the sufferer but also the origin of the whole trouble; and efforts to unravel the skein of symptoms, and to discover the laws in accordance with which they appear, have until recently generally met with indifference if not with ridicule on the part of the profession at large.

It cannot be denied that many if not most hysterical patients exhibit mental and moral obliquity, and that among the evidences of this obliquity appear not infrequently attempts at deceit and signs of disordered imagination; but the tendency of recent investigation is to show that these mental states, instead of causing the whole trouble, are merely symptoms (like, for example, the paralyses and the convulsions) of a disorder in the central nervous system not less real than that of epilepsy, although its exact pathology, like that of epilepsy, is still a matter of conjecture. Certainly some force other than simulation is required to explain such a symptom as persistent cramp holding a young girl's hand or foot for months in a position which the strongest man could not maintain for half an hour, while the absolute recovery of such a hand or foot forces us to class the case under hysteria rather than any organic disease. Such symptoms, as well as the lethargic and cataleptic states, to which hysterical patients are prone, seem, on careful study, to result from the same forces as obtain in health, and to work under the same laws, the difference being one of degree, not kind. For example, the convulsions of hysteria may in a general way be safely regarded as the exaggeration of the lower (cerebral and spinal) reflexes, combined, perhaps, with the depression of the higher cerebral control.

The phenomena of so-called magnetism have long been imposed upon the credulous public, but science has deprived them of much of their mystery, by showing that the same results may be brought about by a single individual upon himself. It has been found, for example, that fixing the sight and attention for some time upon a shining object may produce, in the comparatively healthy individual, a state of catalepsy which will persist after the withdrawal of the object of contemplation. Whatever may be the exact nature of this phenomenon, there can be no doubt that it is en-

[1] Lancet, December 22, 1883, January 5, 12, 1884.

tirely a subjective one; and perhaps we should not fall far from the truth in assuming that continued fixation of the mind on any object is capable of suspending, to a varying degree, the inhibition which the higher cerebral centres exert in health over the lower reflexes directly associated with the movements of the body.

In the case of persons in this state, the change from catalepsy to lethargy, or again to somnambulism, may be brought about by the application of various stimuli; and experiment has shown that the same general laws apply to all "magnetized" subjects in various parts of the world. The degree of susceptibility to these influences varies among healthy individuals, but among hysterical patients this susceptibility is generally marked. A hystero-epileptic may often be thrown into a cataleptic state by the application of a tuning-fork to the forehead or by the sound of a gong.

Rude as the revelation may be to the sensitive believer in the supernatural, it seems probable that most of the mysterious sleepers, whose histories have been handed down to us surrounded by tender associations, religious and sentimental, were simply highly susceptible and sometimes hysterical persons, subject to attacks of prolonged catalepsy or lethargy, the histories of which, translated into medical language of the present day, would be similar to that of the case reported by Professor Gairdner.

ENDOWMENT OF MEDICAL SCHOOLS: BEQUEST OF THE LATE DR. CALVIN ELLIS TO THE HARVARD SCHOOL.

THERE are no institutions in the country in regard to which the question of endowment has more importance than medical schools, and there are none for which less has been done by communities in general or which have been less the recipients of the bounty of individuals.

It is quite generally recognized now, even in our commercial age and country, that a purely commercial basis is not a suitable one upon which to build up the higher branches of learning and teaching; the necessary spur of competition which it supplies can be otherwise provided by better motives; and the day is evidently remote where a stagnating ease and content will be fostered in our medical schools by the large revenues of invested funds. The Medical School of Harvard University and that of the University of Pennsylvania are the only two prominent schools which occur to our mind as owing their buildings and their revenues in any degree to public or private benefactions, and to these the Johns Hopkins School with its hospital will soon be added. It is in these schools that an effort is being made to elevate the system and standard of our medical education. But in each case the possession of a fine, commodious building brings with it not only increased facilities but increased expectations from friends and increased expenditures; and unless accompanied by endowments the erection of buildings, even when representing the generosity of benefactors, may prove a burden rather than an aid to higher aspirations.

It is, therefore, with very great pleasure that we submit to our readers the text of that portion of the will of the late lamented Dr. Calvin Ellis by which Harvard University will, under certain contingencies, as residuary legatee, become trustee for its Medical School of a sum of not less than $150,000. The clauses of the will referred to are as follows: —

"All the residue and remainder of the said trust property my trustees, in the event aforesaid, shall convey in fee-simple, transfer, and pay over to the said President and Fellows to hold the same as a permanent fund, and apply the net rents and income thereof and of all substituted property; in every year, after first deducting and accumulating in every year five per centum of such net income as an increase of the fund towards paying the salary of a professor of pathological anatomy. Provided, however, that if such professor would receive in any one year, if the whole of the said net income remaining after such deduction of five per centum were paid to him, a salary of more than $5000 for such year, arising from gifts, legacies, and other permanent endowments (including the income of this legacy), then, and in every such year, the amount paid him from the income of this legacy shall be reduced so that the total income from such sources shall be $5000 and no more. And if the income from gifts, legacies, and other permanent endowments, exclusive of the income of this legacy, shall amount in any year to $5000, then, and in every such year, the income from this legacy shall be withheld altogether from such professor. The amount so withheld, whether it be the whole or a part of the net income, after deducting five per centum, shall be applied to the salary of the professor of physiology, with the same provisions and limitations as those herein declared touching the salary of the professor of pathological anatomy. And any amount in every such year still remaining unapplied shall next be applied to the salary of the professor of anatomy with the same provisions and limitations as are herein declared touching the salary of the two professors first named. And if the whole or any part of such income still remains unexpended in any year, the same shall be expended in such year for such other purposes in the Medical Department of the said college as the said President and Fellows shall deem most useful."

By the eventual execution of these provisions Dr. Ellis's name would become associated through the succeeding years with the best fruits of the work of a school whose highest interests it was his aim during his life to aid in advancing. Moreover, at the same time that the Harvard Medical School profits by a really handsome and useful endowment, the community at large gains in more ways than one, not the least of these being an example which others not directly connected with our profession should be easily tempted to imitate. In no way can money be made to yield a better interest than in securing for those who seek to enter the medical service of a community all facilities for the best possible training, for "sooner or later

most persons must call upon medical art, for themselves or others, in one of those moments when the physician or surgeon is looked to as an earthly savior." And again we may emphasize what has been said by quoting other words from a communication of Dr. O. W. Holmes to the *Boston Advertiser*, two years since, upon this very subject: —

"A school which depends for its existence on the number of its students cannot be expected to commit suicide in order to satisfy an ideal demand for perfection. Any institution which is essentially dependent on the number of paying students it can draw must be tempted to sacrifice its higher aims to popularity. No high standard can be reached under such circumstances, and the only way to insure the independent action of a school which aims at teaching the whole country by example is to endow its professorships, so that the very best and highest grade of instruction, and not that which is popular, because it is easy and superficial, may always be given from its chairs, whether the classes be large or small. A small number of thoroughly accomplished medical graduates, their knowledge based on sound scientific acquirements, and made practical by assiduous clinical observation and teaching, will be worth more to the country than twice or thrice the number of half-taught, hastily-taught, practitioners. A series of such classes will, in the course of a single generation, elevate the whole professional standard as they go forth, year after year, missionaries in the cause of health, soldiers, and, if need be, martyrs, in the unending battle with disease and its causes."

A NEW ENGLAND CREMATION SOCIETY.

The New England Cremation Society was organized in Boston on the 11th instant, an act of incorporation having been granted not long since. By-laws were adopted and officers chosen. The fee for membership, $1.50 per month, or $12 in one annual payment, insures each member cremation, the only other cost being the delivery of the remains to the crematory. The Society in this city was organized under the clause whereby societies "religious, scientifical, and medical," can issue stock at $25 per share. The capital stock of the company is to be $20,000, and it is the intention to establish a crematory at the earliest opportunity. A site had already been determined on in the suburbs of the city, and situated in most attractive surroundings. Some four acres of land will be, it is understood, taken for the purpose, and will be laid out in a becoming manner. A handsome building will be constructed, containing a chapel, where religious exercises may be held while the body is being incinerated in the retort below. The plan also contemplates a room for autopsies, and others for the keeping of bodies a certain length of time. This latter provision is with the view of easing the minds of those who might wish cremation, but who have a dread of either being buried or burned alive. The Society and its crematory will be open to all classes, irrespective of creed or color, and any services at the chapel will be in accordance with the wishes of the relatives, but free of expense to the Society. The crematory will be the fourth (?) in the world, and it is understood that use will be made of the most advanced ideas already embodied in similar institutions at Gotha, Milan, and in Washington, Penn. As the Society represents New England at large, it is possible that the anticipations of its founders for a fair and growing support may be realized.

RESTRAINT AT THE UTICA INSANE ASYLUM.

In the case of Evan D. Hughes, a patient in the State Insane Asylum at Utica (of which Dr. John P. Gray is the medical superintendent), who died there on the 1st of February, the coroner's jury rendered a verdict to the effect that he came to his death by reason of injuries inflicted on him by three attendants, while engaged in restraining the patient, who was in a state of frenzy, and that the acts of the attendants were in violation of the rules of the institution, and without excuse or justification. In consequence of this verdict the three attendants have each been held in $1000 bail on a charge of manslaughter in the second degree. A member of the coroner's jury makes the statement, however, that a majority of the jurors were of the opinion that the attendants acted in self-defense, and signed the verdict only on the assurance of the District Attorney that it would not hold the defendants. The case has also resulted in the appointment from the State Legislature of a special committee of members of the Assembly to make an investigation of the Utica Asylum and its management.

If such investigation is thought desirable under these circumstances, we hope it may be conducted so as to exclude, as far as possible, the sensational element which has been already too much "worked" in the discussion of asylum management.

MEDICAL NOTES.

— The housemaids are threatened with being deprived of their ancient right of nominal association with bursitis patellæ. Those who have observed how the scrub-woman of the present day does her office have had reason to fear that these leisurely wielders of the long-handled mop would ere long have to abdicate their traditional position in surgical nosology. And now we find that their successors are, of all people, — the clergy! In these days of modern conveniences one can hardly see how the upholstered *priedieu* and tufted hassock can allow the most genuflexionary clerical to develop a hygroma. We have it, however, on the authority of a correspondent of the *Lancet*, who is the attendant of a French Jesuit college in Ireland, that inflammation of the patellar bursa is not at all uncommon. He says that there are about one hundred members of the college, the majority of these being students varying from eighteen to twenty-two years of age, and the average number of cases of

affections of the bursa patellæ has been about five per annum.

— The *Medical and Surgical Reporter* contains the following formula for home-made koumyss, furnished by a druggist, who claims that it is more convenient than any other for domestic purposes: Take of milk one quart, one fourth of a teaspoonful of bicarbonate of soda, one ninth of a cake of compressed yeast, two tablespoonfuls white sugar, three tablespoonfuls glycerine. Rub the yeast up smoothly with a small portion of the milk, and mix all together in a quart bottle, cork tightly, and keep in a temperature from 80° to 100° F. for six hours, then in ice-box for twelve hours, and use.

NEW YORK.

— Mr. and Mrs. Percy R. Pyne, of New York, have presented $100,000 in cash to the Trustees of the Moses Taylor Hospital at Scranton, Penn., to be added to the fund bequeathed for the erection and endowment of the institution. Mrs. Pyne is a daughter of the late Mr. Taylor, who devised $250,000 for the purpose, and this additional gift of $100,000 will enable the managers to carry out the design of the founder, in which there has been a delay on account of the fact that the fund was found insufficient for the completion of the plans adopted.

— The late Dr. Beverley Livingston, a graduate of the Sheffield Scientific School in 1874, requested before his death, last year, that his scientific collections, consisting of a large number of microscopic slides and other specimens, together with the sum of $3000, should be presented to that institution, and his wishes have now been carried out by his father.

— The monthly meeting of the Medico-Legal Society of February 13th was principally devoted to a discussion of a paper recently read before the Society by Dr. J. G. Johnson, on Concussion of the Spine in Railway Injuries.

— At the meeting of the Society of Medical Jurisprudence and State Medicine, held February 14th, Prof. Jarvis S. Wight, of the Long Island College Hospital, read a paper entitled, A Plea for the Just Treatment of Criminals.

— At the annual meeting of the Kings County Pharmaceutical Society, held in Brooklyn, February 13th, a committee was appointed to confer with the authorities of the Long Island College Hospital in reference to the establishment of a school of pharmacy at that institution.

— The Trustees of the College of Physicians and Surgeons have elected Dr. John C. Dalton, for so many years Professor of Physiology, President of the College, in place of Dr. Alonzo Clark, who has resigned. Dr. John G. Curtis now holds the chair of Physiology.

— On the occasion of the fourteenth annual dinner of Bowdoin College Alumni Association of New York, held at Delmonico's February 14th, Dr. Fordyce Barker was reëlected President.

— The turf surrounding the mansion of Mrs. A. T. Stewart, on Fifth Avenue, is said to have been taken from the grounds of the old New York Hospital, at Broadway and Pearl Street, and to be about one hundred years old. When the hospital buildings were torn down some years ago, Mr. Stewart purchased the sod from the Governors, and had it relaid about his new house, which was then in course of erection.

PHILADELPHIA.

— The County Medical Society has for several meetings devoted considerable time to the discussion of the clinical relations of the bacillus tuberculosis. The subject was introduced by a paper read by Dr. H. F. Formad, who spent some time last summer in Koch's laboratory investigating the bacillus theory of consumption. In this communication he admitted the frequent existence of a bacillus in tubercular diseases, but denied that it acted as the sole cause of consumption; in a person already predisposed to tuberculosis, or susceptible to the disease, the bacillus may act as an irritant, and hence in such a case would be the exciting cause of the disease. He contended that consumption is a disease which may be excited by various irritants, of which the bacillus is simply one; for the production of the disease there is required (1) a definite soil, (2) an indefinite irritant. Tubercle he defined as an inflammatory new formation in a special individual or tissue. Testing the theory by clinical experience, he claimed that consumption was neither specific nor contagious; that no cases of well-authenticated contagion which would bear scientific analysis had been reported. As the rule, the predisposition to tuberculosis consists in a peculiar arrangement of the lymph spaces which is met with in certain individuals, and in certain animals, forming what is known as the strumous diathesis; the exception is an inflammation of a serous membrane, which may give rise to tubercle directly, possibly by the establishing of an artificial scrofulous anatomy by blocking up the lymph spaces by fibrine and molecular débris; this, then, would be a mechanical and not an infective process.

In the discussion Dr. E. O. Shakespeare, who will also discuss the subject at the next meeting of the American Medical Association, defended Koch's views, and stated that Dr. Formad had confounded the predisposing with the exciting cause of phthisis; he dissented entirely from the views expressed by the lecturer. Dr. Longstreth believed that too much stress had been laid upon the bacillus, which he could not accept as the sole and sufficient cause of consumption. A number of others expressed just as discordant opinions, which succeeded in establishing at least one fact, that is, the question is still in a thoroughly unsettled condition, and will require time and further observation for its solution.

— Several new societies have been started with more or less promise of a successful career with the beginning of the year. Prof. S. D. Gross presided at a meeting to organize a society for the study of forensic medicine; about fifty physicians and thirty members of the Philadelphia Bar Association have signified their intention of joining the Society, which held a meeting for the election of officers on the third Tuesday of February. A Neurological Association

has just been formed, with Dr. S. Weir Mitchell as president.

— The reception given to Dr. Theophilus Parvin by the Alumni Association of the Jefferson Medical College, on January 28th, was attended by many of the resident graduates of the school and a number of invited guests. It was a very successful and thoroughly enjoyable affair, and gave many an opportunity of making the acquaintance of the recent acquisition to the Faculty, who has already made many friends.

— The annual meeting of the Alumni Association of the Medical Department of the University of Pennsylvania was held January 31st, when Dr. William Hunt, President of the Association, delivered an address abounding in wit and practical wisdom, and full of wise saws and modern instances.

— Philadelphians are subscribing to the Sims memorial. After this fund is complete it would be a very becoming thing for some New York gentleman to suggest that we erect a monument to Isaac Ray and to Thomas S. Kirkbride, or to Washington L. Atlee, or Joseph Pancoast. Are there greater names than these to be found in the annals of American medicine?

— At the last meeting of the College of Physicians Dr. Horatio C. Wood read a paper on the Clinical Aspects of Brain Syphilis, Dr. Wilson contributed a Further Note on the Specific Treatment of Typhoid Fever, and Dr. Harrison Allen described a New Method of Studying the Motions of the Soft Palate.

Correspondence.

RENEWED REQUEST FOR EMBRYOLOGICAL MATERIAL.

Mr. Editor, — Last autumn you kindly published a request for me, stating that I desired to obtain a large embryological material, and I have since received a number of specimens from various gentlemen, to whom I take pleasure in now publicly offering my thanks. Will you not permit me to again renew my request for embryos of all ages, and to add thereto the statement that those which are received in a fresh state within a few hours after the delivery are by far the most valuable, as only by the immediate preservation of the parts is it possible to obtain the nervous and epithelial tissues in a condition suitable for microscopic examination. I believe I can assure the contributors to my collection of fœtuses that all the specimens received will be thoroughly utilized, and be of great value not only to myself but to a large and increasing number of students also. I am preparing a treatise on human embryology, and desire to base the work as far as possible upon original observations on *human* development. Hitherto embryologists have worked principally upon animals.

I shall be very glad to meet any expenses incurred in sending specimens. Where it is impossible to send them in the fresh state it is best to place them in alcohol diluted with one third of its bulk of water.

Yours very truly,

Charles Sedgwick Minot.

Harvard Medical School, *February* 14, 1884.

Miscellany.

THE ORTHOPÆDIC SURGEON AS A MECHANICAL ENGINEER.

Dr. Newton M. Shaffer, in a recent paper on the present status of orthopædic surgery (*New York Medical Journal*, January 26, 1884), takes strong ground as to the necessity for the practitioner of this specialty to furnish specific details of every appliance which he requires, and if necessary to be able to make it, at least to *know how* to make it. He claims that every scientific orthopædist, competent to give to his patients the skill which they have a right to demand, should become responsible for everything pertaining to the manufacture of the instruments to be used. On this point he says: —

"In order to satisfactorily carry out the system of prescribing apparatus for deformities, the instrument maker should be placed in the same category as the pharmacist, and should supply apparatus for deformities only upon a prescription, — that is, a carefully executed diagram of the apparatus needed. But how is an educated orthopædic surgeon to execute this plan? While orthopædic surgery has advanced to the dignity of a well-recognized place in general surgery, the facilities for filling a mechanical prescription are in some respects no better than they were fifty years ago. As a rule, the instrument maker who now fills the prescription of the orthopædic or general surgeon is not unwilling to treat deformity himself, and it not infrequently occurs that he makes suggestions to the patients that are sent to him. There is, I regret to say, some excuse for this, for it has sometimes happened that the instrument maker has a better idea of what is needed than the surgeon who sent the patient to him, for the reason that orthopædic surgery is not, as a rule, taught in our medical schools, and the generally lax way in which chronic deformities are referred to leaves the newly-fledged graduate utterly unprepared to treat them, especially in a mechanical sense. Nor is it at all unusual for the instrument maker to be called in a kind of a consultation by the surgeon, to devise some sort of apparatus to accomplish an ill-defined end in a given case of deformity or disease. Still further, there are scattered throughout the country various agents of the prominent instrument-making firms, druggists, for example, who prescribe for the most serious cases in orthopædic surgery and order an apparatus from a distance about which they know little or nothing, except that gained from the catalogues."

As a contrast to this method of treatment and to the practice of those surgeons who, after making a diagnosis, turn the case over to a mechanic, as if there were something degrading and unprofessional in attending personally to the details of the mechanical department of orthopædic work, he describes the method pursued in the New York Orthopædic Dispensary. Here there is, in direct connection with the institution, a fully equipped mechanical room in which four or five men are constantly employed making apparatus directly under the instructions of the surgeons; no apparatus is made without a drawing, and careful measurements accompanied by actual outlines, when necessary, are given with every order; no repairs are made except by personal instruction of the surgeons, accompanied by drawings if necessary. A similar shop, supplied with steam power, has been established in connection with the University Hospital at Philadel-

phia, where apparatus is made after drawings by the surgeons and under their supervision. We are informed that the entire cost of the shop did not exceed $2000, which includes a building erected for the purpose, and that it is now nearly self-sustaining, actual cost of production only being charged to those patients who are able to pay it.

RECENT METHODS OF TREATING COLD ABSCESSES.

PROFESSOR BILLROTH thus writes on the above subject (*Medical Press and Circular*, January 16, 1884): When we turn our thoughts to a cold abscess we must first of all place before ourselves the questions, Why is not the contained fluid absorbed? and why are we compelled either to await its opening or open it ourselves?

Exudations that arise in the course of acute inflammations, or transitory disturbances of circulation, are indeed usually absorbed; if the general condition of the body is in other ways normal, the absorption of the fluid is the ordinary process. If you have a clear conception of the arrangement of the lymphatic vascular system you will comprehend this, for the lymphatic vascular system sucks up all these exudation products like a sponge, and carries them all back into the blood channels. Under what conditions, then, does this resorption fail to take place? (1.) You may say first that absence of open lymph vessels is a very important cause, and that is just the case with the capsule that in the course of time forms around these abscesses. The walls of the veins can, it is true, take up some of the fluid, but it is the open lymph vessels that are most concerned in such absorption. But even when such open lymph courses are present, they may become closed under certain circumstances, as by an exudation that becomes clotted, in which fibrine forms quickly, and in which the clotting may be continued into the lymph vessels, or into the interstitial structural interspaces. This is the case to a great extent in croupous and diphtheritic exudations. (2.) The resorption is dependent on the degree of concentration of the fluid. If the fluid is to be resorbed, its concentration must be less than that of the blood. That is not the case in cold abscesses. Moreover the various regions of the body show great differences in their power of resorption; the pelvis is the most favorable for resorption; the most unfavorable is the pleural cavity. How can we overcome these difficulties therapeutically? (1.) The first method would be the removal of the fluid; but experience teaches that the fluid may be removed for the moment, but that the exudative property of the structure does not cease; on the contrary, the cavity refills with uncommon rapidity with pus, this refilling being principally caused by the fact that by removal of the fluid the vessels in the abscess walls are subjected to a greatly reduced pressure. (2.) Is it possible by certain irritating agents to excite a greater vascularity in the walls of the abscess? With this object in view tincture of iodine has been injected, for the purpose of exciting an inflammation, whereby an exudation is certainly set up, but which, in consequence of the higher vascularity thus induced, is readily absorbed, with the result that the cavity shrinks up. (3.) This method was succeeded by the opening of the abscess under strict antiseptic precautions. Not only is the pus evacuated, but the abscess cavity is carefully scraped with the sharp spoon, after which an antiseptic dressing is applied. In this way the walls of the abscess, which consist of a mass of soft granulations, are removed as far as the healthy tissues, whereby, by means of a light compress, healing by first intention has been achieved. Indeed, by this method good results have been obtained in many cases, but it is one that requires to be carried out with great accuracy. Since the introduction of iodoform we have strewn the scraped-out cavity with iodoform in powder, and brought the edges together with the exception of the openings left for drainage. By means of iodoform sepsis is to a great extent avoided, and under certain circumstances granulations may spring up under which healing rapidly takes place. (4.) Quite recently we have attempted another method, namely, puncture of the abscess, and subsequent injection of an emulsion of iodoform consisting of ten parts of iodoform to 100 parts of glycerine. The emulsion must be well shaken up before using, and then, according to the size of the abscess, twenty to thirty grammes are to be injected. In most of the cases in which this method has been attempted the course has been free from reaction, only moderate swelling has taken place, and but little pain has been present. This, however, would only indicate that the treatment has done no harm; it is also desirable that it should bring about the shrinking of the abscess, and that the fluid remaining in the cavity should be absorbed. As a matter of fact, the results in some cases were exceedingly favorable, but further experience is necessary to show whether the iodoform emulsion is still to be continued. Generally speaking, I should advise you, unless there should be some reason for it, not to open the cold abscess, but to allow it to open spontaneously, especially if you cannot watch over your patients closely. You can then calculate with certainty that the pus will escape without fever and without further reaction, whilst at the same time the entrance of air is completely avoided. In such cases the mechanical relations are extremely favorable, even wonderfully so, without our being able to give an explanation of them, for it happens, for example, that an abscess bursts into the bladder or rectum, and in such cases I have never seen urine or intestinal gases enter the abscess cavity. Under strict antiseptic precautions, and under your constant supervision, you may open the abscess, especially if you suspect with some certainty that you can easily reach the bone from which the abscess springs, or if it causes by its great expansion compression of the neighboring structures, and in consequence of this gives rise to various difficulties.

THE SACRED WHITE ELEPHANT.

THE Siamese minister in London announces, *apropos* of Mr. Barnum's white sacred elephant from his country, that the existence of sacred elephants, white or black, is altogether unknown in Siam. The dermatologists of London, on the other hand, say that such pretensions — and they are limited — as the beast can make to being white are based on a disease, leucoderma. Robbed of the attributes of sacredness and whiteness it becomes simply an elephant with a disordered skin.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 9, 1884.

Deaths reported 2725 (no reports from Cincinnati and Buffalo): under five years of age, 1007: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 466, consumption 434, lung diseases 347, diphtheria and croup 151, scarlet fever 72, diarrhœal diseases 55, typhoid fever 47, measles 30, malarial fevers 26, whooping-cough 25, cerebro-spinal meningitis 22, puerperal fever 14, erysipelas 14, small-pox 10. From *diarrhœal diseases*, New York 19, New Orleans nine, St. Louis seven, Boston six, New Haven five, District of Columbia three, Baltimore two, Brooklyn, Chicago, Providence, Nashville, and Charleston one each. From *measles*, District of Columbia nine, New York and Baltimore seven each, Brooklyn three, Philadelphia, St. Louis, Nashville, and Charleston one each. From *malarial fever*, New Orleans nine, New York eight, Brooklyn three, Chicago, Baltimore, and St. Louis two each. From *whooping-cough*, New York 10, Philadelphia, Brooklyn, and Boston three each, Chicago, Baltimore, St. Louis, Worcester, Gloucester, and Haverhill one each. From *cerebro-spinal meningitis*, New York nine, Chicago four, Philadelphia two, New Orleans, District of Columbia, Lowell, Lawrence, Salem, Newton, and Brockton one each. From *puerperal fever*, Chicago five, New York and Boston two each, Brooklyn, Baltimore, Milwaukee, Fall River, and Springfield one each. From *erysipelas*, Chicago three, Baltimore, New York, and New Orleans two each, Philadelphia, Brooklyn, Boston, St. Louis, and Lynn one each. From *small-pox*, New Orleans nine, Nashville one.

Three cases of small-pox were reported in St. Louis; scarlet fever 51, diphtheria 24, typhoid fever eight, and measles two in Boston; scarlet fever 22 and diphtheria six in Milwaukee.

In 95 cities and towns of Massachusetts, with an estimated population of 1,277,688 (estimated population of the State 1,922,530), the total death-rate for the week was 19.26 against 16.59 and 17.78 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending January 26th, the death-rate was 20.3. Deaths reported 3410: acute diseases of the respiratory organs (London) 360, whooping-cough 130, scarlet fever 97, measles 86, fevers 48, diarrhœa 27, diphtheria 26, small-pox (London and Birmingham two each) four. The death-rates ranged from 15 in Norwich to 26.8 in Manchester; Bradford 15.9; Leicester 16.9; Bristol 17.7; Blackburn 18.4; Sunderland 19.1; Nottingham 19.3; Birmingham 19.6; London 19.9; Liverpool 22; Sheffield 24.1; Leeds 25.5. In Edinburgh 18; Glasgow 22.7; Dublin 24.5.

For the week ending January 12th, in 170 German cities and towns, with an estimated population of 8,688,664, the death rate was 25.5. Deaths reported 4269; under five years of age, 1909; consumption 647, lung diseases 492, diphtheria and croup 271, scarlet fever 75, measles and rötheln 71, typhoid fever 67, whooping-cough 54, puerperal fever 35, small-pox (Lubec one) one. The death-rates ranged from 11.8 in Wiesbaden to 52 in Duisburg; Königsberg 33.5; Breslau 30; Munich 30.8; Dresden 34.2; Berlin 24.9; Leipzig 26.9; Hamburg 27.3; Cologne 24.1; Frankfort a. M. 18.5; Strasburg 23.4.

For the week ending January 26th, in the Swiss towns, there were 28 deaths from consumption, lung diseases 27, diphtheria and croup 10, puerperal fever four, whooping-cough four, scarlet fever three, measles two, small-pox one, typhoid fever one. The death-rates were, at Geneva 20.6; Zurich 29.5; Basle 26.3; Berne 21.1.

The meteorological record for the week ending February 9th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM FEBRUARY 9, 1884, TO FEBRUARY 15, 1884.

To be assistant surgeons, with the rank of first lieutenant, to date December 3, 1883: —

William D. Dietz, Walter W. A. Fisher, William Stephenson, Adrian S. Polhemus, John L. Phillips, Reuben L. Robertson, William C. Borden, Edgar A. Mearns, Guy L. Edie, William D. Crosby, William L. Kneadler, Charles M. Gandy, Charles S Black, James E. Pilcher, Alonzo R. Chapin. S. O., A. G. O., Washington, February 11, 1884.

BREWSTER, WILLIAM B, first lieutenant and assistant surgeon. Resignation accepted to date February 7, 1884, S. O., A. G. O., Washington, February 11, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING FEBRUARY 16, 1884.

COUES, S. F., medical director, to the Naval Medical Examining Board, Philadelphia, March 3d, as the relief of Medical Director P. J. Horwitz, who retires on that date.

SUFFOLK DISTRICT MEDICAL SOCIETY. SPECIAL MEETING. — The *Section for Clinical Medicine, Pathology, and Hygiene* will meet at 19 Boylston Place, on Wednesday, February 27th, at 7.45 o'clock. Dr. J. Cheston Morris, of Philadelphia, will present a paper on The Milk Supply of Cities and Large Towns. Mr. Lloyd F. Abbott will read a paper on The Milk Supply of Boston and the Benefit to be Derived from the Spaying of Cows.

ALBERT N. BLODGETT, *Secretary.*

ERRATUM.

BOSTON, *February* 15, 1884.

MR. EDITOR, — It may seem a small matter, but, in quoting Wordsworth, I want to avoid errors. "The child is father *of* the man," not "*to*," as given in your last number, is the correct line.

Yours truly,

H. I. B.

BOOKS AND PAMPHLETS RECEIVED. — The Surgical Treatment of Tumors and other Obscure Conditions of the Bladder. By Walter Whitehead, F. R. C. S. E., F. R. S. Edin., Surgeon, Manchester Royal Infirmary and the Manchester and Salford Lock and Skin Hospital, and Bilton Pollard, M. D., B. S., F. R. C. S., Resident Surgical Officer Manchester Royal Infirmary. Original Articles.

THE TREATMENT OF RETROVERSION OF THE UTERUS WITH ADHESIONS.[1]

BY J. W. ELLIOT, M. D.,
Assistant Surgeon Free Hospital for Women.

This malady has been and is still considered by many incurable. Thomas,[2] referring to adhesions, says "this is one of the conditions which render the prognosis" of retroversion "unfavorable." All the other text-books of the day are equally discouraging, and none of them lay down a definite mode of treatment. In my own experience I have found these cases curable. I therefore venture to describe a method by which favorable results may be obtained. This method consists, in brief, in repeatedly packing the posterior vaginal cul-de-sac with tampons in such a manner that the adhesions being gradually stretched, broken, and absorbed, the uterus is pushed into its normal position.

This method is by no means new. Dr. Bozeman claims to have used it before 1860. Dr. Taliaferro[3] first described it in a paper read before the Medical Association of Georgia, in 1878, on The Application of Pressure in Diseases of the Uterus. I understand also that this method has been used by a few New York specialists and several of my colleagues in Boston. I first learned it from Dr. Baker, who has practiced it for several years with most satisfactory results, and to him I owe many of my opportunities for investigating its value. This general method has, then, been employed by a few physicians with variable results. The details of the procedure have differed in more or less essential points with all. Without discussing these differences I shall simply describe the particular method which I now use after three years' experience. First let us consider what the course of this disease is when not treated.

When the uterus becomes retroverted from any cause it is lower in the pelvis, and drags more or less on the twisted broad ligaments, which contain the large arteries and veins which supply that organ. This causes a passive congestion in the uterus. This means increased size and weight. The increased size and weight cause in turn increased dragging; thus we have a "pernicious circle" established. The ultimate result of long-continued passive congestion is an increase of interstitial tissue. Here, then, we have a condition which tends to grow worse. This may give rise to quite a disagreeable set of symptoms, namely, feelings of dragging, of pressing down of the abdominal contents, and a sense of weight. The increased vascularity gives rise to increased menstrual flow, to increased secretion from the glands and mucous membrane (fluor albus), and to increased sensitiveness of uterus and vagina. The bladder being more or less displaced there is often frequent and difficult micturition. The rectum may be obstructed by the fundus uteri so as to cause difficult or painful defecation. The peritoneal surface of a uterus in this condition often becomes inflamed. If this occurs the result may be that the uterus becomes more or less firmly fixed by peritoneal adhesions; in which case the above-mentioned symptoms are, of course, increased. Not only this but when the uterus is once fixed in retroversion by adhesions successive attacks of local peritonitis usually follow. These attacks may recur after any slight provocation, such as jarring, going about during menstruation, taking cold, etc., until the patient is exhausted by pain or general peritonitis is imminent. She is then obliged to go to bed, where she will often improve for a time, but when she gets up the local peritonitis usually begins again, and she finds herself no better than before. This sort of thing may go on for years or the patient sometimes gives up trying to go about, and becomes a confirmed bed-ridden invalid. This disease is associated with great pain and tenderness in the vagina and all about the pelvis, causing inability to walk and a decline in the general health. The nervous system suffers as a matter of course. It very often causes sterility, and should the uterus by chance become impregnated a miscarriage is almost certain to follow, the common result of which is another sharp attack of local peritonitis with more adhesions. If, however, a miscarriage does not occur and the patient goes to full term, the adhesions are gradually absorbed as the uterus increases in size.

From this we see that retroversion with adhesions is a progressive disease; that it tends to grow worse when there is no treatment.

Next let us inquire into the more exact nature of these adhesions.

The peritonæum of the female pelvis may become inflamed at any point where it covers the various pelvic organs, so one speaks of perisalpingitis, pericystitis, periproctitis, perimetritis, etc. Usually inflammation of several of these organs is present at once. Then one speaks of pelvic peritonitis in distinction on the one side from general peritonitis, on the other from parametritis or pelvic cellulitis, by which last name we mean inflammation of the cellular tissue (including vessels and veins) just under the peritonæum. Inflammation of the peritonæum is associated with the exudation of fluid and the formation of fibrous adhesions. When pus is exuded it is often shut off by membranes between the uterus and rectum, then either the pus fatty degenerates, and is absorbed, or the abscess breaks. When the abscess is emptied healing takes place by the union of its two walls, which are the uterus and the rectum. In this way the uterus may become retroverted and bound firmly to the rectum by a very dense mass of adhesions. Vide Fig. 1.

Fig. 1. (Winckel.) *D*, Douglas's Fossa obliterated by a mass of adhesions, the result of an abscess. *B*, Bladder. *V*, Vagina. *U*, Uterus. *R*, Rectum.

The membranes resulting from peritonitis may become like ligaments, and bind the uterus to the rectum. Vide Fig. 2. When two inflamed surfaces of peritonæum on different organs come in contact they are often glued together. In this way the least firm adhesions are formed. Adhesions vary greatly in size and toughness. The large, tough ones are the result

[1] Being the subject-matter of a lecture delivered at a Summer Course in Boston and cases reported at the Boston Society for Medical Observation, February 4th.
[2] Diseases of Women, page 438.
[3] Atlanta Medical Register, January, 1883.

of often repeated attacks of peritonitis. If no fresh attack occurs the adhesions tend to disappear very slowly. From being constantly stretched and worn by the respiratory and other movements they may finally be absorbed. In spite of this fact many adhesions persist for a lifetime, hence their importance to gynæcologists.

Parametritis usually occurs in the broad ligaments and is, therefore, most often the cause of lateral displacements and adhesions. These lateral adhesions,

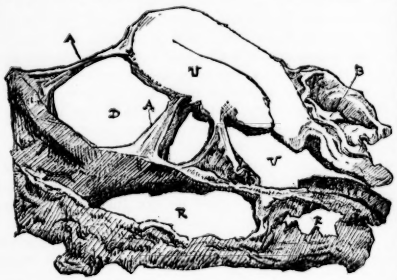

FIG. 2. (Winckel.) *A A*, Adhesions on the stretch. *D*, Douglas's Fossa.

being formed by cicatricial contractions of interstitial tissue, are much firmer and tougher than those resulting from simple peritonitis, which occur in connection with retro and anteversions. These two processes (peritonitis and parametritis) may occur together, and cause a right or left retro-lateral version.

The causes of this disease are various. Merely the condition of retroversion may be the cause of a local peritonitis, and hence adhesions. Also, having a retroversion a local peritonitis from any cause may result in adhesions. Any local peritonitis may form such adhesions about a uterus in normal position as to cause retroversion. The causes of local peritonitis are, then, the causes of adhesions. Among such causes Heitzmann [1] considers irregularity and other anomalies in menstruation as common. Hence any change in uterus, tubes, or ovaries which causes such irregularities, as stenosis, congenital anteflexion, etc., also taking cold during menstruation. Any catarrhal inflammation of the uterus may extend through the tubes to the peritoneal cavity. This most frequently happens with gonorrhœal endometritis. Ovaritis itself may be a cause, also the rupture of a Graafian follicle. The rubbing of a prolapsed ovary may be a cause. Parametritis may cause peritonitis by direct extension. There are various traumatic causes, such as direct injury to peritonæum, falls, coition, vaginal douche, pessaries, and any intra-uterine instrumentation, passing a sound or dilating with tents. Septic absorption from wounds of uterus or vagina may cause septic peritonitis. The last and most common cause is parturition and abortion.

The diagnosis of retroversion with adhesions is arrived at by first establishing the presence of a retroversion (by touch or probe), the adhesions may then be felt through the posterior vaginal cul-de-sac. Vide Fig. 4. In certain cases their presence can only be determined by a failure to replace the uterus by the various well-known maneuvers. A strong firm adhesion is evident, and cannot easily be overlooked. The difficulty is that one not skilled in reducing retroversion may sometimes be led to suppose that the uterus is adherent when it is merely pressed down and caught behind the promontory of the sacrum. This mistake will, however, soon become evident if the treatment here described be applied.

There are four methods of treating this disease: —

(1.) Forcibly tearing up adhesions under ether at one sitting.

(2.) Gradually stretching and tearing the adhesions by lifting the body of the uterus with the finger a little at each sitting.

(3.) Gradually lifting the body of the uterus by a series of pessaries, beginning with a very small one; larger ones are placed as the uterus is lifted higher.

(4.) Packing as here described.

I prefer the last of these methods for most cases, because it seems to me the surest and safest.

To pack the vagina the patient must be placed in the semi-prone or knee-chest position. I use the latter position in the more difficult cases, and the former in ordinary cases, as it is much easier for the patients. A Sims' speculum being passed, small bits of cotton, wrung out in glycerine, are then packed into the posterior vaginal cul-de-sac. Each bit is placed with dressing forceps held in the right hand. It is then pressed back as hard as occasion may require with the blade of the speculum held in the left hand. Vide Fig. 3. When the posterior cul de-sac is full, the vagina

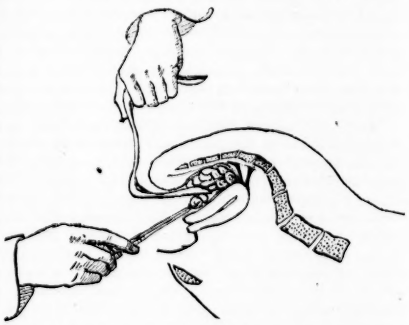

FIG. 3. Manner of placing the Cotton Tampons.

is then packed full of the same tampons to hold those placed in the cul-de-sac tight up against the fundus of the uterus. At the outlet of the vagina the cotton is pressed back toward the rectum, away from the point where the urethra passes under the pubic arch, as pressure on that point may cause retention. The last two pieces of cotton should be rather larger than the others, and one should be pushed to the right and the other to the left, so that when the patient stands and pressure comes from above these two pieces wedge each other like the stones in an arch and keep the packing from falling out. The packing being thus placed piece by piece, the result should be that, as a whole, the mass will exactly conform to the shape of the vagina, exerting a firm, even, and constant pressure against the fundus uteri. It will of course require some practice to do this well. The packing should be removed every three to five days, with the patient in the same posi-

[1] Beckenbauchfells Entzündung.

tion. On removing the packing we find the post-vaginal cul-de-sac somewhat deeper, for the pressure when properly applied tends always to wedge the uterus away from the rectum. Before replacing the packing it is a good plan to try to determine how much has been gained and where the adhesions still bind. This is best done while the patient is in the semi-prone position by hooking the cervix forward with a tenaculum held in the left hand, then passing the forefinger or two fingers of the right hand high up into the posterior vaginal cul-de-sac (the palm being toward the patient's back), and pressing the uterus forward with the back of the finger. In this way the adhesions can be put on the stretch over the ends of the fingers, and a good

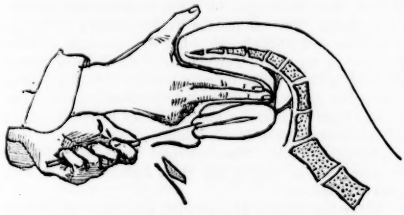

Fig. 4. Method of detecting the Adhesions.

estimate of their strength and position be formed. Vide Fig. 4.

We then proceed to repack the vagina as before. The pressure should be exerted directly backwards into the posterior cul-de-sac against the remaining adhesions. If the force is directed too far forward the result is that the cervix and bladder are raised and tipped forward, while the fundus remains fixed and unmoved. The ability to get the pressure exactly in the right direction is a matter of skill, and requires practice. The question of how tight the packing is to be must remain a matter of judgment in each case at each packing. This judgment will depend upon the condition of the vaginal wall and upon the increasing or diminishing tenderness of the adhesions. In a general way it is best to begin with a light packing, and increase the pressure each time until you pack as hard as you can, unless some contra-indication becomes manifest. The possible dangers from too tight packing are peritonitis and sloughing or rupture of the vagina. As a matter of experience most men pack too loose rather than too tight. Even when there is considerable tenderness a well fitting tight packing gives the most relief.

Some patients get immediate relief when the first packing is applied, and are perfectly comfortable during the whole treatment. Others have constant pain and discomfort. If the treatment is painful the patient must be very carefully managed. A nervous woman, who has often had attacks of pelvic peritonitis, will complain loudly, and actually say that she is sure you have started the inflammation again. It is sometimes very difficult to distinguish between hyperæsthesia and real tenderness. In such cases, when you have decided that there is no increasing local peritonitis, it is important to persist with the packing in spite of their protestations. One soon learns the peculiarities of each individual. It is, of course, very important to stop packing at the slightest indication of increasing or fresh local peritonitis. I have known of several severe cases of peritonitis followed by abscess, etc., which was caused by packing. I have never had this misfortune myself, and it seems to me entirely unnecessary. It may, however, become a very delicate and difficult problem in the case of a feeble and nervous patient to begin with a light packing, making sure that you are doing no harm, and at the same time holding your patient under strict and strong control, to push the treatment forward, packing tighter and tighter, until the uterus is forced into its normal position. No routine can be laid down for such cases.

The packing must be removed before each menstruation.

The treatment is to be continued until the fundus uteri can be pushed well forward; the uterus can then easily be held in position by a pessary. If, however, the adhesions are very resisting and the patient becomes somewhat run down by the treatment, a convenient time to rest is when the fundus has been raised just above the promontory of the sacrum. At this point the uterus can be held for a time with a Thomas' bulb pessary or with a soft rubber bulb pessary. The pressure of the packing may cause constipation; if so, the bowels must be regulated by a cathartic.

As before stated, the packing acts by mechanically forcing the posterior vaginal cul-de-sac up into Douglas's fossa, and thus separating uterus from rectum. Some of the adhesions are torn off, others are so stretched and pulled that being deprived of blood supply they finally wither and are absorbed

The packing is applied as above stated in the knee-elbow or semi-prone position, when the contents of the pelvis are hanging forward into the abdomen and the vagina is at its greatest length. Consequently, when the upright position is resumed, we have a mass of cotton wedging its way up behind the fundus uteri and the weight of all the organs tending to pull the cervix downwards. These two forces twist the retroverted uterus into its normal position.

The uterus, as above stated, having become passively congested, is large and tender. The packing exerts an even pressure against the organ, which partially empties it of blood, so that when the packing is removed the cervix appears smaller and wrinkled. The packing acts in this respect like a well-applied bandage on a swollen limb, and often gives in this way the greatest relief. As the uterus becomes less congested and is raised higher in the pelvis, the attacks of perimetritis (before referred to) become less frequent and less severe, and finally do not recur. The carefully-applied pressure seems also to exert a favorable influence on the inflamed peritoneal surface. I have of late become so impressed with this fact that I now often begin packing when there is considerable tenderness, and I find that this treatment is frequently much the quickest cure for chronic local peritonitis.

I have used various materials for these tampons, but I prefer cotton pluggets wrung out in glycerine. In packing I dip every fourth or fifth plugget in iodoform to keep the packing sweet. Where the adhesions are very firm I sometimes use bits of compressed sponge wrapped in cotton cloth. The sponge swells and exerts a very powerful pressure. I prefer to have the patients walk about during the treatment, for I think in this way the adhesions work loose faster. But certain debilitated cases I have kept in bed.

The general health is usually somewhat pulled down during the treatment; on the other hand it is often im-

proved by the immediate comfort caused by relief from dragging, etc.

It is hoped that this manner of packing will not be confounded with the ordinary cotton pessary for simple retroversion, or with the practice which is not uncommon among physicians of loosely placing a few tampons in the vagina. This sort of thing is, of course, entirely inadequate. The method here described is intended for the treatment of an important disease, and when really firm adhesions are present the packing must be delicately and understandingly applied, each bit of cotton being placed with precision, otherwise it is worse than useless.

The cases here reported were treated at the Free Hospital for Women, the Boston Dispensary, and in my own private practice.

I am greatly indebted to Drs. Davenport and Green, of the Dispensary, for their kind permission to use the records of the cases as they passed to and from my treatment when the terms of service changed.

Out of 1500 gynæcological patients who have come under my observation and treatment within the last three years, there have been eighty-nine cases of retroversion with adhesions, is about .06. Of these cases, two, occurring in old women without symptoms, were advised against treatment, four are still under treatment, and seem to me to be curable, sixteen disappeared without treatment and sixty-seven were cured. By cured I mean here that the adhesions were so dissipated that the uterus is held in its normal position with a pessary, and that the patients have been free from the recurring attacks of pelvic peritonitis. Two of these cases have relapsed after removing the pessary against my directions. In two cases I have already removed the pessary, and the uterus remains in good position. Two cases have become pregnant after several years of sterility.

The length of time required for the treatment of these cases has varied from one month to three years.

The most troublesome complication has been prolapse of the ovaries. In twelve cases there was prolapse of one or both ovaries. With this complication it is necessary to proceed much more slowly. Prolapsed ovaries are almost always very sensitive, and the packing must be placed with great care until they are pushed to one side. Lacerated cervix was a common complication. This condition was invariably much improved by the pressure of the packing. Lacerated perinæum was occasionally an annoying complication on account of the difficulty in keeping the cotton in place. In no case, however, was it found necessary to sew up the perinæum before overcoming the adhesions. In one or two debilitated patients with ruptured perinæums the vagina, after being stretched by the packing, was left in a very flabby condition. This subinvolution of the vagina gradually disappears in a few months.

The change of life came about in one case, aged thirty-five, during treatment.

In one case at the Free Hospital the whole pelvis was filled with a mass of false membranes. The uterus was so imbedded in this mass that there seemed to be adhesions on every side. For three years this case was treated for several months in each year. The uterus is now movable and held in good position with a pessary, and the patient does all her own housework.

The patients have all been more or less relieved of their symptoms. Some have been restored to good health. Some were left in a very nervous condition. The few who had been bed-ridden were put on to their feet again and seemed delighted.

By way of illustration I will give the records of one case: —

CASE I. On November 3d Mrs. B. was referred to me by Dr. James Minot. She was large and stout, but in very poor general health, being much run down, was forty-three years old, had been married twenty-four years, had had three children, and eleven or twelve miscarriages. She complained of wind and pain in the abdomen, of fullness and distress after eating, of vomiting, also of a soreness in the left lower abdomen, which at times became so severe that she was obliged to go to bed, and of dragging about pelvis and abdomen, of a bearing-down pain, frequent and painful micturition. The catamenia were natural; there was a profuse white discharge. On examination I found the uterus enlarged, retroverted, and tightly bound down by a large mass of very tender adhesions, subacute pelvic peritonitis, and chronic endometritis. The uterine cavity was three and a quarter inches deep. I advised rest and the hot douche.

November 10th. She returned in about the same condition. The vagina was then lightly packed with cotton tampons.

November 14th. The packing was removed and not replaced on account of approaching catamenia. The patient was ordered to rest in bed during menstruation.

November 21st. The vagina was repacked.

November 26th. The patient is much relieved of her pain and tenderness. The uterus was found somewhat higher in the pelvis and the adhesions less tender. Vagina repacked.

December 1st. The patient has wet her feet and caught cold, complains of pain and tenderness across her abdomen, but is not as sore as she usually is after taking cold. The adhesions were slightly tenderer, vagina hot and dry. Vagina repacked moderately tight.

December 5th. Much less tenderness. Uterus quite movable. Vagina repacked tightly.

December 8th. Uterus quite freely movable. Can be pushed into normal position. A block tin pessary was placed.

December 20th. Pessary holds uterus in good position. Patient is much relieved in every way.

CLINICAL ASPECTS OF CEREBRAL SYPHILIS.[1]

BY HORATIO C. WOOD, M. D.,

Professor of Diseases of the Nervous System in the University of Pennsylvania.

IN the present article I propose to say very little in regard to the lesions of cerebral syphilis, only making such allusions as are necessary to the clinical study. So much practical importance attaches to the ætiological relations of the disorder that I shall discuss these at some length.

We do not know why syphilis attacks one portion of the brain rather than another in any individual case; indeed, very rarely can we give any sufficient explanation why the brain is affected at all.

It is naturally to be expected that any cause of

[1] Read before the College of Physicians of Philadelphia, February 6, 1884.

ordinary brain inflammation would, when present in a syphilitic person, tend to precipitate a specific cerebral disease. Thus, as thermic fever frequently provokes chronic meningitis, much plausibility attaches to the report of a case in the *Journ. de Méd. et Chir. prat.*, Paris, 1879, page 291, where the cerebral syphilis is ascribed to a sunstroke. Blows and other traumatisms would, in a similar manner, be supposed to figure largely as exciting causes of brain syphilis; but I have never met with a case having such relations, and reports of them are rare in literature. The only records I have found are the cases reported by Dr. Broadbent, *London Lancet*, 1876, ii., p. 741, and a small collection in Huebner's article on Nervous Syphilis, in Ziemssen's Encyclopædia, xii., 301. I have seen two cases of presumably traumatic spinal syphilis: one in which a polio-myelitis [1] followed a fall on the ice, and one in which, after a fall from a cart, and marked spinal concussion, a local myelitis developed.[2]

Various authorities attach much influence to overstudy and other forms of cerebral strain in exciting brain syphilis. Engelstedt is stated to have reported cases having such ætiological relations, and Fournier [3] affirms that he has especially seen the disease in professional men and other persons habitually exercising their brains to excess. Neither in private or public practice have I met with any instance where over-brain work could be considered a distinct ætiological factor, whilst the wards of the Philadelphia Hospital and the roll of the University Dispensary are full of cases occurring in persons who use not at all the modicum of brains nature has endowed them with. So far as my observation goes, cases of brain syphilis in which any exciting cause can be found are very rare.

The inherited diathesis is less prone to manifest itself in the nervous system than in other portions of the body, but it certainly is capable of causing every type of nervous disease that follows infection from impure coition.

As early as 1779 Dr. Jos. Glenck [4] reported a case of a girl, six years old, cured by a mercurial course of an epilepsy of three years' standing, and of other manifestations of hereditary syphilis. Graefe found gummatous tumors in the cerebrum of a child nearly two years old.[5] Prof. O. Huebner [6] details the occurrence of pachymeningitis hæmorrhagica in a syphilitic infant under a year old. Dr. Hans Chiari [7] reports a case in which very pronounced syphilitic degeneration of the brain-vessels was found in a child fourteen months old. Both Dr. Barlow [8] and Dr. T. S. Dowse [9] report cases of nerve syphilis in male infants of fifteen months.

It is a matter of great interest to know how late in life nervous disease from inherited taint may develop. We have, as yet, little light upon the equally interesting and cognate problem as to how far inherited syphilis may produce late in life nervous diseases whose type is not distinctly specific, but it is probable that even after puberty specific nervous affections may appear for the first time in the unfortunate offspring of syphilitic parents. Mr. Nettleship reports [10] the development of a cerebral gumma in a girl of ten years, and Mr. J. A. Ormerod [11] of a tumor of the median nerve (probably gummatous) in a woman of twenty-three, both the subjects of inherited syphilis. Dr. Thomas S. Dowse [12] details a case of cerebral gumma at the age of ten years, and Dr. Samuel Wilks [13] one of epilepsy from inherited taint in a boy of fourteen. Dr. I. Hughlings Jackson reports [14] paraplegia with epilepsy in a boy of eight, hemiplegia in a girl of eighteen, and in the *British Medical Journal*, May 18, 1872, hemiplegia in a woman of twenty-two; the nervous affection in each case being associated with or dependent upon inherited syphilis. Dr. E. Mendel reports [15] a case of a child who had inherited syphilis, and developed in her fifteenth year a maniacal attack with hallucinations.

Some time since I saw, in an orphan of fourteen, a chronic basal meningitis, and, in the absence of any history, gave the fatal prognosis of tubercular disease, but to my astonishment, under the long-continued use of iodide of potassium, complete recovery occurred. No signs of inherited syphilis were perceptible, but the specific nature of the inflammation is, in view of the result, scarcely doubtful; it is probable that in some of the reported cases of alleged recovery from tubercular meningitis the affection has really been syphilitic.

The relation of inherited syphilis to idiocy appears to be a close one. What rôle the diathesis has in the production of those cases which are dependent upon arrest of development we have no way at present of knowing, but that it very frequently causes chronic hydrocephalus seems to be well established. A number of cases have been reported; they have been collected by Dr. E. Mendel.[16]

Nervous diseases following acquired syphilitic infection certainly belong to the advanced stages of the disorder. Huebner reports [17] a case in which thirty years elapsed between the contraction of the chancre and the nervous explosion. I have seen a similar period of thirty years. Fournier reports intervals of twenty-five years, and thinks from the third to the tenth year is the period of maximum frequency of nerve accidents.

The fact that cerebral syphilis may occur many years after the cessation of all evidence of the diathesis is one of great practical importance, especially when taken in conjunction with the circumstance that the nervous system is more prone to be attacked when the secondaries have been very light than when the earlier manifestations have been severe. I have repeatedly seen nerve syphilis in persons whose secondaries have been so slight as to have been entirely overlooked or forgotten, and who honestly asserted that they never had had syphilis, although they acknowledged to gonorrhœa or to repeated exposure, and confessed that their asserted exemption was due to good fortune rather than chastity.

To show that my experience is not peculiar, I may

[1] In this case the man had symmetrical specific skin eruptions upon the arm, and the symptoms were peculiarly symmetrical; great coldness of both fore-arms; excessive sweating of the palms; loss of power, so much more pronounced in the extensors than elsewhere that the patient had been treated for lead-poisoning and great wasting of the extensor muscles. Evidently a symmetrical syphilis chiefly confined to the anterior spinal cornua.

be allowed to make the following citations: Dr. Dowse [1] says: "Often have I had patients totally ignorant of having at any time acquired or experienced the signs or symptom of syphilis in its primary and secondary stages, yet the sequelæ have been made manifest in many ways, particularly in many of the obscure diseases of the nervous system." Dr. Buzzard [2] reports a case of nervous syphilis where the patient was unconscious of the previous existence of a chancre or of any secondaries. Professor Rinecker also calls attention [3] to the frequency of nervous syphilis in persons who afford no distinct history of secondary symptoms.

This frequent absence of history of specific infection is of great practical importance, and has led me to attach comparatively little weight to the statements of patients. In private practice I usually avoid asking questions which might bring up from the past unpleasant memories, and arrive at the diagnosis by studying the symptoms present.

Although syphilis is most prone to attack the nervous system many years after infection, it would be a fatal mistake to suppose that brain disease may not rapidly follow the occurrence of a chancre. What is the minimum possible intermediate period we do not know, but it is certainly very brief, as is shown by the following cases of this so-called precocious cerebral syphilis. Dr. Alfrik Ljunggrén, of Stockholm, reports [4] the case of H. R., who had a rapidly-healed chancre in March, followed in May of the same year by a severe headache, mental confusion, and giddiness. Early in July H. R. had an epileptic attack, but he was finally cured by active antisyphilitic treatment. Although the history is not explicit the nervous symptoms appear to have preceded the development of distinct secondaries other than rheumatic pains.

Davaine is said [5] to have seen paralysis of the portio dura "a month after the first symptoms of constitutional syphilis." Dr. E. Leyden [6] found advanced specific degeneration of the cerebral arteries in a man who had contracted syphilis one year previously. Dr. R. W. Taylor details a case in which epilepsy occurred five months after the infection.[7] In the case of M. X., reported by Dr. Ad. Schwarz,[8] headache came on the fortieth day after the appearance of the primary sore, and a hemiplegia upon the forty-sixth day. S. L.[9] had a paralytic stroke, without prodromes, six months after the chancre. A. P. L.[10] had an apoplectic attack seven months after the chancre; A. S. one five months after her chancre. In a case which recently occurred in the practice of Dr. A. Sydney Roberts, of this city, the chancre appeared after a period of incubation of twenty-six days, and two months and eight days subsequent to this came the first fit; eight days after the first the second convulsion occurred, with a distinct aura, which preceded by some minutes the unconsciousness. The further details of this case are not germane to the present discussion, which only requires the additional statement that the attack developed into an unmistakable cerebral syphilis, with temporary aphasia, and that convalescence was finally secured by active antisyphilitic treatment. As the first paroxysm came on without warning, whilst the man was fishing in the sun, it is not unwarrantable to suppose that a precocious cerebral syphilis was in this case precipitated by exposure to the ordinary causes of sunstroke. This list of cases might be much extended, but it certainly is sufficient to show that cerebral syphilis occurs not very rarely within six months after infection, and may be present in two months.

An interesting observation in this connection is that of Dr. Ern. Gaucher [11] of a spinal syphilis occurring six months after the appearance of a chancre.

Syphilographers are in accord in regard to the existence of two pathological varieties of brain syphilis, whilst some authorities believe in a third form. The most common seat of attack is the membranes; next to these are the brain vessels, whilst, as already intimated, there is difference of opinion as to whether the disease ever directly affects the brain tissue. Reasons will be given later on for believing that the brain substance may suffer violence from syphilis, but I shall first discuss the clinical aspects of specific disease of the membranes.

DISEASE OF BRAIN MEMBRANES.

Specific affections of the brain membranes very often declare themselves with great suddenness. The records of the disease present case after case in which an apoplectic attack, a convulsive paroxysm, a violent mania, or a paralytic stroke, has been the first detected evidence of syphilitic cerebral disease. On the other hand, in many instances the symptoms come on slowly and successively. Proper treatment, instituted at an early stage, is usually successful, so that a careful study of these prodromes is most important. They are generally such as denote cerebral disturbance, and, although they should excite suspicion, are not diagnostic except as occurring in connection with a specific history or under suspicious circumstances.

Headache, slight failure of memory, unwonted slowness of speech, general lassitude, and especially lack of willingness to mental exertion, sleeplessness or excessive somnolence, attacks of momentary giddiness, vertiginous feelings when straining at stool, yelling, or in any way disturbing the cerebral circulation, alteration of disposition, any of these, and *a fortiori*, several of them, occurring in a syphilitic subject, should be the immediate signal of alarm, and lead to the examination of the optic disks, for in some cases the eyeground will be found altered even during the prodromic stage. Of course if choked disk be found the diagnosis becomes practically fixed, but the absence of choked disk is no proof that the patient is not suffering from cerebral syphilis. In regard to the individual prodromic symptoms, my own experience does not lend especial importance to any one of them, although, perhaps, headache is most common. There is one symptom which may occur during the prodromic stage of cerebral syphilis, but is more frequent at a later stage, a symptom which is not absolutely characteristic of the disease, but which, when it occurs in a person who is not hysterical, should give rise to the strongest suspicion. I refer to the occurrence of repeated, partial, passing palsies. A momentary weakness of one arm, a slight drawing of the face, disappearing in a few hours,

a temporary dragging of the toe, a partial aphasia, which appears and disappears, a squint, which to-morrow leaves no trace, may be due to a non-specific brain tumor, to miliary cerebral aneurisms, or to some other non-specific affection, but in the great majority of cases where such phenomena occur repeatedly the patient is suffering from syphilis or hysteria.

The first type or variety of the fully formed syphilitic meningeal disease to which attention is here directed is that of an *acute meningitis*. I am much inclined to doubt whether an acute syphilitic meningitis can ever develop as a primary lesion, whether it must not always be preceded by a chronic meningitis or by the formation of a gummatous tumor, but it is very certain that acute meningitis may develop when there have been no apparent symptoms and may, therefore, seem to be abrupt in its onset. Some years ago I saw, in consultation, a man who, in the midst of apparent health, was attacked by violent meningeal convulsions, with distinct evidences of acute meningitis. He was apparently saved from death by very heroic venesection, but after his return to consciousness developed very rapidly a partial hemiplegia, showing that a latent gumma had probably preceded the acute attack. On the other hand, an acute attack is liable at any time to supervene upon a chronic syphilitic meningitis. At the University Hospital Dispensary I once diagnosticated chronic cerebral syphilis in a patient who, the next day, was seized with violent delirium, with convulsions and typical evidences of acute meningitis, and died four or five days afterwards. At the autopsy an acute meningitis was found to have been engrafted on a chronic specific lesion of a similar character. In the case reported by Dr. Gamel,[1] in which intense headache, fever, and delirium came on abruptly in an old syphilitic subject, and ended in general palsy and death, the symptoms were found to depend upon an acute meningitis, secondary to a large gumma.

In this connection may well be cited the observation of Dr. Molinier,[2] in which violent delirium, convulsions, and coma occurred suddenly. A very curious case is reported by Dr. D. A. Zambaco,[3] in which attacks simulating those of acute meningitis appear to have been produced in a man with a cerebral gummatous tumor by a malarial complication. In such a case the diagnosis of a malarial paroxysm could only be made by the presence of the cold stage, the transient nature of the attack, its going off with a sweat, its periodical recurrence, and the therapeutic effect on it of quinine.

In the cases of *chronic meningeal syphilis* which have come under my observation, most usually after a greater or less continuance of prodromes, such as have been mentioned, epileptic attacks have occurred with a hemiplegia or a monoplegia, which is almost invariably incomplete, and usually progressive; very frequently diplopia is manifested before the epilepsy, and on careful examination is found to be due to weakness of some of the ocular muscles. Not rarely oculomotor palsy is an early and pronounced symptom, and a marked paralytic squint is very common. Along with the development of these symptoms there is almost always distinct failure of the general health, and progressive intellectual deterioration, as shown by loss of memory, failure of the power to fix the attention, mental bewilderment, and, perhaps, aphasia. If the case convalesce under treatment the amelioration is gradual, the patient traveling slowly up the road he has come down. If the case end fatally it is usually by a gradual sinking into complete nerve-paralysis, or the patient is carried off by an acute inflammatory exacerbation, or, as I saw in one case, amelioration may be rapidly occurring, and a very violent epileptic fit produce a sudden asphyxia. In this form of cerebral syphilis death from brain softening around the tumor is not infrequent, but a fatal apoplectic hæmorrhage is rare.

The clinical varieties of cerebral meningeal syphilis are so polymorphic and kaleidoscopic that it is almost impossible to reduce them to order for descriptive purposes. Professor Fournier separates them into the cephalic, congestive, epileptic, aphasic, mental, and paralytic, but scarcely facilitates description by so doing. Huebner makes the following types: —

"(1.) Psychical disturbances, with epilepsy, incomplete paralysis (seldom of the cranial nerves), and a final comatose condition, usually of short duration.

"(2.) Genuine apoplectic attacks with succeeding hemiplegia, in connection with peculiar somnolent conditions, occurring in often-repeated episodes; frequently phenomena of unilateral irritation, and generally at the same time paralyses of the cerebral nerves.

"(3.) Course of the cerebral disease similar to paralytica dementia."

In regard to these types the latter seems to me clear and well defined, but contains those cases which I shall discuss under the head of cortical disease.

Meningeal syphilis as seen in this country does not conform rigidly with the other asserted types, although there is this much of agreement that when the epilepsy is pronounced the basal cranial nerves are not usually paralyzed, the reason of this being that epilepsy is especially produced when the gummatous change is in the ventricles or on the upper cortex. In basal affections the epileptoid spells, if they occur at all, are usually of the form of petit mal, but this rule is general, not absolute. The apoplectic, somnolent form of cerebral syphilis, for some reason, is rare in this city, and it seems necessary to add to those of Professor Huebner's a fourth type, to which a large proportion of our cases conform. This type I would characterize as follows: —

(4.) Psychical disturbance without complete epileptic convulsions associated with palsy of the basal nerves and often with partial hemiplegia.

The most satisfactory way of approaching this subject is, however, to study the important symptoms in severalty, rather than to attempt to group them so as to make typical, recognizable varieties of the disease, and this method I shall here adopt.

Headache is the most constant and usually the earliest symptom of meningeal syphilis; but it may be absent, especially when the lesion is located in the reflexions of the meninges, which dip into the ventricles, or when the basal gumma is small and not surrounded with much inflammation. The length of time it may continue without the development of other distinct symptoms is remarkable. In one case,[4] at the University Dispensary, the patient affirmed that he had had it for four years before other causes of complaint appeared. It sometimes disappears when other manifes-

[4] Book Y, page 88, 1879.

tations develop. It varies almost indefinitely in its type, but is, except in very rare cases at least, so far paroxysmal as to be subject to pronounced exacerbations. In most instances it is entirely paroxysmal, and a curious circumstance is that very often these paroxysms may occur only at long intervals; such distant paroxysms are usually very severe, and are often accompanied by dizziness, sick stomach, partial unconsciousness, or even by more marked congestive symptoms. The pain may seem to fill the whole cranium, may be located in a cerebral region, or fixed in a very limited spot. Huebner asserts that when this headache can be localized it is generally made distinctly worse by pressure at certain points, but my own experience is hardly in accord with this. Any such soreness plainly cannot directly depend upon the cerebral lesion, but must be a reflex phenomenon, or due to a neuritis. According to my own experience, localized soreness indicates an affection of the bone or of its periosteum. In many cases, especially when the headache is persistent, there are distinct nocturnal exacerbations.

It will be seen that there is nothing absolutely characteristic in the headache of cerebral syphilis; but excessive persistency, apparent causelessness, and a tendency to nocturnal exacerbation, should in any cephalalgia excite suspicion of a specific origin; a suspicion which is always to be increased by the occurrence of slight spells of giddiness, or by delirious mental wandering accompanying the paroxysms of pain. When an acute inflammatory attack supervenes upon a specific meningeal disease, it is usually ushered in by a headache of intolerable severity.

When the headache in any case is habitually very constant and severe, the disease is probably in the dura mater or periosteum, and this probability is much increased if the pain be local and augmented by firm, hard pressure upon the skull over the seat of the pain.

Disorders of Sleep. — There are two antagonistic disorders of sleep, either of which may occur in cerebral syphilis, but which have only been present in a small proportion of the cases that I have seen. Insomnia is more apt to be troublesome in the prodromic than in the later stages, and is only of significance when combined with other more characteristic symptoms. A peculiar somnolence is of much more determinate import. This may occur in non-specific leptomeningitis, and in states of altered brain nutrition from senile or other degenerations of the walls of the cerebral vessels, and is therefore not pathognomonic of cerebral syphilis, yet of all the single phenomena of the latter disease it is the most characteristic. Its absence is of no import in the theory of an individual case.

As I have seen it, it occurs in two forms: In the one variety the patient sits all day long or lies in bed in a state of semi-stupor, indifferent to everything, but capable of being aroused, answering questions slowly, imperfectly, and without complaint, but in an instant dropping off again into his quietude. In the other variety the sufferer may still be able to work, but often falls asleep while at his tasks, and especially towards evening has an irresistible desire to slumber, which leads him to pass, it may be, half of his time in sleep. This state of partial sleep may precede that of the more continuous stupor, or may pass off when an attack of hemiplegia seems to divert the symptoms. The mental phenomena in the more severe cases of somnolency are peculiar. The patient can be aroused, indeed in many instances he exists in a state of torpor rather than of sleep; when stirred up he thinks with extreme slowness, and may appear to have a form of aphasia; yet, at intervals he may be endowed with a peculiar automatic activity, especially at night. Getting out of bed, wandering aimlessly and seemingly without knowledge of where he is, and unable to find his own bed, passing his excretions in a corner of the room, or in other similar place, not because he is unable to control his bladder and bowels, but because he believes that he is in a proper place for such act, — he seems a restless automaton rather than a man.

Apathy and indifference are the characteristics of this state, and yet the patient will sometimes show excessive irritability when aroused, and will at other periods complain bitterly of pain in his head, or will groan as though suffering severely in the midst of his stupor, at a time, too, when he is not able to recognize the seat of the pain. I have seen a man with a vacant apathetic face, almost complete aphasia, persistent heaviness and stupor, arouse himself when the stir in the ward told him that the attending physician was present, and come forward in a dazed, highly pathetic manner, by signs and broken utterance begging for something to relieve his head. Huebner speaks of cases in which the irritability was such that the patient fought vigorously when aroused; this I have not seen.

This somnolent condition may last many weeks. Dr. T. Buzzard [1] details the case of a man who, after a specific hemiplegia, lay silent and somnolent for a month, and yet finally recovered so completely as to win a rowing match on the Thames.

In its excessive development, syphilitic stupor puts on the symptoms of advanced brain softening, to which it is indeed often due. Of the two cases with fatal result of which I have notes, one at the autopsy was found to have symmetrical purulent breaking down of the anterior cerebral lobes; the other, softening of the right frontal and temporal lobes due to the pressure of a gummatous tumor, and ending in a fatal apoplexy.

This close connection with cerebral softening explains the clinical fact that apoplectic hæmorrhage is very apt to end the life in these cases of somnolent syphilis. Dr. Buzzard's case given above and others which might be cited prove, however, that a prolonged deep stupor in persons suffering from cerebral syphilis does not prove the existence of extensive brain softening, and is not incompatible with subsequent complete recovery. As an element of prognosis, it is of serious but not of fatal import.

(*To be concluded.*)

REPORT ON MATERIA MEDICA.

WILLIAM P. BOLLES, M. D.

ABRUS PRECATORIUS, L. (INDIAN LIQUORICE, PATER NOSTER BEANS, JEQUIRITY, BLACK-EYED SUSANS, ETC.)

THIS plant is by no means new to botanists nor its products to commerce. It was named by Linné, and has had a place in the pharmacopœias of India for forty years, the root, however, being the only part

[1] Clinical Lectures on Dis. Nerv. Syst., London, 1882.

used in medicine. It is a papilionaceous plant, doubtfully placed in the tribe *Viciæ* of the order *Leguminosæ*, a small woody twiner with abruptly pinnate, many-pinnuled leaves, and rose-colored flowers in rather close racemes. The pods are smaller than those of the sweet pea, clustered, four to six seeded. The seeds, considerably smaller than the pea seeds, are roundish ovoid, of a brilliant scarlet color, with a black patch around the hilum, covering about one third of the surface; they are hard and beautifully polished. The plant is indigenous in India, but is found in almost all tropical countries, probably introduced.

The root is used to a small extent in India as a poor substitute for liquorice root. The seeds are used as toys or strung into necklaces or rosaries. They are favorite curiosities with our sailors, and as a consequence were often seen in our sea-ports long before they had any commercial value here.

A full botanical description of the plant, with plate, may be seen in Bentley and Trimen's Medicinal Plants, and of the root, "*Radix abri*," in the Pharmacographia.

The root as well as the leaves contains a sweet principle resembling liquorice, and is destitute of any poisonous or deleterious quality. The seeds have not been thoroughly examined, but are non-poisonous, and have even been used in Egypt as food.

The present interest in the plant centres, however, in the application of the seeds, in infusion or decoction, to trachomatous eyes for the purpose of producing a substitutive conjunctivitis. According to Dr. Moura Brazil, the seeds have been employed for many years in the Brazilian provinces of Ceará and Piauhy for chronic granular conjunctivitis. They are usually prepared by soaking them for a few hours in boiling water, or for a few days in cold water, then blanched, and the kernel reduced to a fine powder, which is macerated for twenty-four hours and filtered. This liquid is applied beneath the eyelids three times a day. The proportion of one part of *jequirity* to twenty of water, the skin and radicle being removed, produces a moderate inflammation, but if all the parts of the seed are used the irritation is most intense.

Dr. Silva found what he supposed to be conidia of some fungus in the fresh infusion, and the mycelium and spores of the same in an older specimen. The same organisms were found in and could be developed from the conjunctival products.[1]

It was introduced into European practice by M. de Wecker, who received a sample of seeds from a patient who, after a long and unsuccessful treatment in Paris, returned to Brazil, and was there cured by this local remedy. The directions accompanying the sample were the following: Take thirty-two seeds (about three grammes), macerate them for twenty-four hours in five hundred cubic centimetres of cold water, then add the same quantity of warm water, filter, and the fluid is ready for use. The infusion changes from green to brown, and finally to yellow, without, however, becoming completely putrid.

Professor Sattler (Sadtler?) found that the symptoms did not vary greatly with the strength of the infusions, a one half per cent. solution producing symptoms almost as severe as one ten times as strong, but that a fresh preparation was much more efficient than one forty-eight hours old, and one prepared at the ordinary temperature than one prepared at a considerably higher one (85° F. to 96° F.). The decoction of the pulverized seeds he found to be inoperative.

The symptoms following the use of jequirity are as follows: The application is painless, and for several hours no sensations follow, then a sense of fullness followed by injection of the conjunctiva and lachrymation appear; then a thin film forms upon the conjunctival surfaces, which, however, is superficial, and can be wiped off without hæmorrhage. By the next day the eyelids are swollen and closed, and the conjunctiva is covered with lymph and pus. General disturbance is often present to a considerable degree, and restlessness and pain almost always. Coryza is a not infrequent accompaniment. This condition lasts five or six days, and then gradually disappears. The cornea is not apt to be, but is occasionally attacked. As the traumatic inflammation passes away the chronic trouble is found to be very much improved.[2]

THE DRASTIC AND VESICATING ELEMENTS OF CROTON OIL SEPARABLE.

The partial or variable solubility of croton oil in alcohol is a long observed fact. The Pharmacographia says: "Its solubility in alcohol (.794) appears to depend in great measure upon the age of the oil and the greater or less freshness of the seeds from which it is expressed, oxidized or resinified oil dissolving the most readily."

M. Harold Senier has succeeded in separating completely the vesicating and purgative principles from each other by means of alcohol. He says: "When alcohol (specific gravity 794–800) is mixed in equal volumes with English pressed croton oil perfect and permanent solution takes place, and this is equally true when any less quantity of alcohol is used. When, however, the proportion of alcohol to oil is as seven to six or any larger proportion of alcohol then a part of the croton oil separates, and cannot afterwards be dissolved by any amount of alcohol. The other portion, on the other hand, is soluble in all proportions of alcohol."

The remarkable feature of the observations is that the alcohol-soluble portion appears to contain all the vesicating principle, and the insoluble the cathartic element of the crude oil. Dr. Meek experimented with the non-vesicating, and found that doses of from one tenth to one half of a drop produced the cathartic action of croton oil without any irritation or other disturbance, the smaller dose being a mild, and the larger a powerful, purgative, unaccompanied by any unpleasant symptoms. The vesicating (soluble) oil in the same doses gave no purgation, but occasioned a considerable amount of nausea and irritation. The latter readily produced pustulation when applied to the skin, the other did not. Further study indicated that the real vesicating element was one of the combined fatty acids, but the author has not yet succeeded in isolating it.

The above observations if supported by clinical experience will greatly increase the value of this remedy as a purgative.[3]

ARBUTIN; UVA URSI.

Dr. Lewin[4] claims to have proved that all the value of uva ursi is due to the arbutin contained in it; that

[1] New Remedies.

[2] Therapeutic Gazette.

[3] Pharmaceutical Journal.

[4] Therapeutic Gazette.

the latter can be given as safely and more efficiently than the other; that both are eliminated in part as hydrochinon in the urine; and that the antizymotic and antiseptic qualities of this latter are the secret of their value in vesical catarrh. (Hydrochinon is a whitish powder, allied to resorcin and pyrocatechin; it is also found in the urine in phenol poisoning.)

The writer states that urine of patients taking uva ursi is discolored to a greater or less degree by the hydrochinon, and "that it remained fresh after standing in the open air for two weeks, while that subsequently voided rapidly decomposed." He recommends that the dose of uva ursi be increased to from thirty to eighty grammes in decoction, filtered through animal charcoal to remove the tannic acid; or, still better, the substitution of arbutin in one gramme (?) doses be used instead.

The price of arbutin, fifty cents per gramme, will prevent its being a very popular remedy, although as it is found in a number of Ericaceæ the supply might be increased.

QUASSIIN.

Although known in a crystalline form for many years the processes for extracting it have been either difficult or wasteful, and all the commercial quassiin has been in the condition of extract. MM. Adrian and Moreaux[1] have proposed a new process by which they obtain a larger quantity, 0.8 per cent. of an amorphous "quassiin," a friable product consisting of not quite half pure quassiin (crystallizable and uncrystallizable); by further purification they obtained 0.125 to 0.150 per cent. of pure white crystals. The amorphous quinine left behind in the mother liquor is about as bitter, and, for all that we know, as good as the other.

The drug examined was the Surinam quassia from *Quassia amara*, L., which is used in France more than that which constitutes the quassia of the United States and Great Britain, but the two drugs appear to be identical in their activity.

CONVALLARIA.

Prof. E. Maragliano[2] made the following observations on Convallaria.

He employed it as an aqueous and alcoholic extract, also its derivatives, convallarin and convallamarin, using it in thirteen cases of valvular (especially mitral) insufficiency, all with the symptoms of cardiac weakness.

In nine cases the result was favorable, and in a few superior even to digitalis; in four cases it had no effect, but neither had digitalis. Convallamarin showed itself the most powerful.

By continued use it increased the secretion of urine, and lowered the frequency of pulse and respiration without otherwise altering it.

The experiment of making use of it in increasing the secretion of urine for the reabsorption of pleuritic exudations failed in the nine cases tried.

The doses given were one to two grammes of the extract, in an indifferent vehicle, daily; of convallarin or convallamarin 0.25 grammes to one gramme daily (0.50 grammes was sufficient in most cases) in pills of about 0.05 grammes each.

[1] Rep. de Pharm., copied in Pharmaceutical Journal.
[2] Archiv der Pharmacie.

COLOCYNTHIN.

Herr Gustav Henke,[3] in a communication to the Pharmaceutical Institute of Strasburg, gives a short history of the previous investigations upon the active principle of colocynth, and his own.

The purest form in which he was able to obtain it was as a "brittle, resinous mass (Mercks' is a softish black extract), making a dry yellow powder, permanent in the air. It is neutral, soluble in twenty parts of cold water, freely so in diluted, and sparingly in absolute, alcohol. Insoluble in chloroform, ether, etc.

He was unable to attain to Waltz's success in obtaining it in crystalline form, although he prepared it after Waltz's method, as well as his own, and he considers the glucoside decomposition, commonly believed, to be erroneous.

He obtained scarcely thirty grammes of the active principle from five kilos of colocynth pulp, or about 0.6 per cent.

PRESERVATION OF GREEN HERBS.

Dr. F. I. B. Quinlan read before the British Pharmaceutical Conference two papers[4] upon preserving green pulps by what he calls ensilage; that is, pounding to a pulp, packing hard, sealing in bottles, and burying deep in the ground. The herbs, in a perfectly fresh state, are bruised to a pulp in a mortar, and then placed in glass bottles, being well tamped down, and filled to the very stopper, so as to exclude all the air. They were then sealed with beeswax, and buried three feet below the ground. Belladonna, conium, and other herbs were kept in this way four months, "perfectly sweet and fit for pharmaceutical purposes." Dr. Quinlan had not, however, at the time of his report, tried the products of his "ensilage," and so the most important claim of the experimenter, the therapeutical value of the products, needs yet to be maintained.

THE AMOUNT OF IODINE IN COD-LIVER OIL.

Mr. Edward C. Stanford[5] has just gone over this much-contested ground, and reached the conclusion that the amount of iodine has heretofore been very much overestimated. The mean of six samples in his hands, and carefully examined, was 0.000322.

GELATINE BANDAGE, TRAUMATICINE, ETC.

Dr. Pick[6] has been employing a glue varnish as a protective coating for cases of chronic eczema, psoriasis, etc. It consists simply of a strong solution of gelatine, or fine glue, painted over the affected parts with a brush, and made flexible by a little glycerine rubbed over its surface after it is dry.

For the same purpose Professor Auspitz has proposed a chloroformic, ten per cent., solution of gutta percha. Both these substances are transparent, and permit the surface to be readily seen. If they should crack or peel they can be easily repaired.

GELSEMINE.

Mr. A. W. Gerrard,[7] F. C. S., has succeeded in obtaining this amorphous alkaloid, of which the purest form has hitherto been Sonnenschein's brownish-yellow powder, in imperfect but unmistakably crystalline

[3] Archiv der Pharmacie.
[4] Pharmaceutical Journal.
[5] Ibid.
[6] Ibid.
[7] American Journal of Pharmacy.

form, and several of its salts, also crystalline. It is white, in "granular" crystals, sparingly soluble in boiling water, from which it separates upon cooling, and differs in its color reactions with acids, and its chemical composition, from that of Sonnenschein.

CHINOLIN, KAIRIN, ETC.

These interesting artificial relatives of the cinchona alkaloids have received a considerable amount of attention from chemists and physiologists during the past year or two. The most promising of these is "kairin," so called. It is a grayish-white powder, with a saltish, bitter, aromatic taste, not very unpleasant, reminding one a little of salicylate of soda. In doses of 0.5 gramme to one gramme it distinctly lowers the febrile temperature for two or three hours, and is followed by sweating. The article is at present rather but not excessively costly, and can be easily obtained in the larger cities by those who wish to use it.

PERFECTLY PURE PHENOL.

Another gain in the manufacture of carbolic acid has been made by a firm in Eisenbüttel, who have produced pure, clear, colorless, *dry, and separate crystals* of this universally used substance. They are less deliquescent than the ordinary crystalline masses; the solution is white, and does not change by light. To every test for purity it excels anything heretofore made.

TANRET'S ERGOTININE.

There is an article upon this alkaloid in the *Pharmaceutical Record* for January, 1884, by M. Tanret himself, in which he defends its value and explains its administration. Although he has obtained the alkaloid in crystalline form, it is not perfectly unchangeable, and he only offers it in syrup and solution. Of the former a teaspoonful, representing 0.00025 of the alkaloid, is the average dose of the solution. For hypodermic use five drops represent the same amount.

Reports of Societies.

NEW YORK COUNTY MEDICAL ASSOCIATION.

ÆTIOLOGY OF TYPHOID FEVER.

At a stated meeting, held February 18th, Dr. E. G. Janeway read a paper on the above subject. He said that in rural districts and in institutions typhoid fever seemed not infrequently to spread by contagion, as person after person sickened with the disease; yet in not a few of these instances it could be shown that such contagion was not direct, but indirect. It could not but be admitted that very few cases would stand a rigorous examination and be capable of proving that the disease was spread by direct contact. In order to arrive at a just conclusion in this matter an inquiry had been made at several hospitals receiving typhoid-fever patients, and the result was in the main negative. All claimed that no nurse or patient in the wards contracted the disease; but in one, some years ago, one of the physicians contracted typhoid fever while residing in the hospital, and in another a domestic sickened with the disease. The small number of cases occurring among those resident in hospitals treating typhoid-fever patients would, therefore, point towards failure of disinfection or to defect in the plumbing of the institution where such cases had occurred.

The principal source of typhoid fever in New York City was to be looked for in defective sanitary arrangements, permitting the entrance of the emanations of the sewers either to the air or to the drinking-water of which the patient made use. It was a great mistake, however, to suppose that invariably when sewer emanations gained entrance to a house, and even when the defects were very great, typhoid fever would appear. The writer had seen marked exceptions to such an idea, which, together with the susceptible character of those exposed, only proved that something more was necessary than ground saturated with water and sewage in order that typhoid fever should occur. In cases of typhoid it was not always easy to decide how the poison gained entrance to the system. If we supposed that germs were floating in the air, the question must be raised, Do they occasion the disease by being received through respiration and taken into the lungs, or are they by this act simply drawn into the mouth and throat, and thence swallowed with the saliva, food, and drink, to develop in the alimentary canal? To the writer the latter method seemed the more probable. Any one who had examined much the sanitary defects in cases of typhoid fever would find that vitiation of water was in many cases possible, especially at the present time, when the water supply and water pressure were both defective in New York. The drawing of water on a lower floor caused a partial vacuum, which, if stop-cocks were open, or if tanks supplied by ball-floats, which opened the pipe when the water was lowered, were employed, or if there were defective valves to pipes in water closets with direct supply, caused an aspiration of air into the water pipes of the house. The writer had traced outbreaks of typhoid fever in two institutions to sanitary defects of this nature and operating in this way. Having alluded to other sources of danger in connection with water pipes, he went on to say that a large number of privy vaults were still attached to the tenement houses in New York, and that there was but one form of these places which was devoid of danger, the school sink or trough closet. In such houses in a large city the question of the origin of cases of typhoid fever, with or without the germs from preëxisting cases of the disease, was as impossible of a just decision as in the case of defective sewage. That these privy vaults served to develop the poison of typhoid fever there was sufficient evidence, and the method of action might be in one of three directions: (1) by the use of the place, (2) by the leakage from such place, causing saturation of the soil beneath a house, and (3) by the connection of the living rooms of a house with such places by waste pipes. For several years the Board of Health had refused to allow any new privy vaults to be constructed; but under the law the tenement-house owner had the option of a trough closet or some form of water closet, and the writer had feared that with the defective water supply, and consequent deficient flushing of soil-pipes, an increase of typhoid fever might result from the introduction of water closets in the tenement houses on a large scale.

In the upper portions of the city of New York wells, with all the attendant liability of sewage-pollution, were still in use to a considerable extent, and the writer had been able to trace the outbreak of typhoid fever in an institution to use of such water by the em-

[1] Pharmaceutical Record. Translation from Pharm. Centralhalle.

ployment of the chloride of lithium test. In this connecton Dr. Janeway gave an account of the outbreak of typhoid fever at Princeton College, in regard to which he had made a thorough investigation. The origin of the trouble was traced to a house within which there was a water-closet discharging into a cess-pool with earth sides and bottom, in a shale soil, forty feet distant from a well, the water of which was found, on chemical analysis, to be seriously polluted. Afterwards the disease was ascertained beyond a doubt to have spread not by the drinking water, by the air, or by direct contact, but by means of the emanations from the sewer and cess-pool into which the passages from those sick with the fever had been thrown without disinfection. As regards the question of origin of this outbreak, whether spontaneous or from a previous case, the writer had been unable to come to a positive conclusion. Other avenues by which the disease might be introduced in a house, and of which the writer had seen possible, though not positive, illustrations, were, by means of refrigerators having direct sewer connection and by contaminated milk and food. He had been able to connect one outbreak in the upper districts of New York with affected milk, possibly diluted with water coming from a contaminated well, as in the cases reported from abroad, especially from England.

Dr. Janeway had reached the following conclusions with reference to the ætiology of typhoid fever:—

(1.) That it is in all probability due to a bacillus.

(2.) That this virus is certainly contained in the discharges from the bowels.

(3.) That it gains entrance to the system through the air coming from places into which the discharges of other typhoid-fever patients have been deposited, or through water contaminated by a similar process, or through milk diluted with contaminated water, or perhaps vitiated by contaminated air.

(4.) That there are instances which point to the probability that the germs which produce typhoid fever may develop in a suitable soil, but not have been derived from a preëxisting case of the disease.

(5.) That it is not necessary to invoke the aid of the rise and fall of the ground water to explain the disease; though a low state of the ground water, by favoring an increase of the impurities in a well or water-supply, may favor the spread of the disease, as may also a sudden severe rain after a drought, by washing impurities, including the germ of the disease, into the drinking water.

(6.) That the failure of the disease to spread when prompt and thorough disinfection of the excreta has been performed, as well as of clothing soiled by such discharges, makes it extremely doubtful whether the disease is communicated by the respiration, perspiration, etc.

(7.) The writer has had no opportunity to study outbreaks of fever resembling typhoid, such as have occasionally been met with abroad, due to the eating of diseased meat.

The writer said that accompanying the paper were tables which would give in detail the number of deaths which had been ascribed in New York to each of a number of febrile diseases since 1852. In each of the last four years more deaths were ascribed to the malarial class of diseases than to typhoid fever; and this he thought was due to error in diagnosis, since in Bellevue Hospital 653 cases of malarial fever had been treated during the last three years, with a mortality of only three, or one death for each year. Among the fevers referred to, from 130 to 154 deaths in each year were reported as due to the hybrid, typho-malarial fever, and, as far as New York City was concerned, the writer regretted the employment of this term. It had led to confusion, and had also prevented those proper measures from being employed which would prevent the spread of typhoid fever and lead to an investigation of its causes. He had long insisted that the evidence of post-mortem examinations was opposed to the use of this term here, and he had known cases which clinically seemed, and were asserted to be, typical of this combination, which only presented the ordinary anatomical conditions of typhoid fever. The concluding part of the paper was devoted to a consideration of the relationship of age to the development of typhoid fever, and of the question whether the disease were increasing or not.

DR. A. FLINT, SR., said he had listened to the paper with great interest, and was glad that the subject had been brought before the Association. At the present time preventive medicine was of greater importance than therapeutic, and our ability to protect the public from typhoid fever, which was a purely preventable disease, depended, of course, on our knowledge of its ætiology. There was every reason to suppose that typhoid fever was developed from a special cause, which produced this particular disease, and no other, just as the eruptive fevers were. Whether this were a germ, or something else, had not as yet been definitely determined; but, reasoning from analogy, it was fair to assume that the disease did depend on a special organism. It was desirable to know, then, whether this special cause, whatever its nature might be, was always derived from the body of a patient ill with typhoid fever, or whether it could not originate spontaneously under certain circumstances. Here, again, it was not possible in our present state of knowledge to say positively; but, reasoning still from analogy, we would infer that the germ, as it might be called for convenience' sake, at all events, always did come from the body of a patient. One point of great practical importance was that this germ was capable of preserving its activity for a considerable period — at least two years. It seemed to be well established that it entered the system in two ways: (1) in the drinking water, or other liquid mixed with water, and (2) by the inspiration of contaminated air. In New York the infection was probably almost always conveyed by contaminated air, and the manner in which this was effected could generally be traced to some defect in plumbing or sewerage. This was why the disease ought to be preventable. It seemed to be the fact, however, that typhoid fever was increasing in New York, and one reason for this, in addition to the defective sanitary provisions found in many houses, was probably the present deficient water supply.

In every case of this disease to which a physician was called it behooved him to ask, What is the cause of the trouble? and the cause, he thought, could almost always be ferreted out if a thorough investigation were made. But in case the physician failed in his duty in this respect, he believed that it was the business of the Board of Health to make such an investigation in every single case of typhoid fever reported to them. In this way a great deal might be accomplished towards the prevention of the disease.

In regard to typho-malarial fever, he was a little

at variance with the author of the paper. He thought that this was a good term, as he believed that even in New York it was not uncommon to find the typhoid fever poison in combination with a malarial element. Dr. Janeway looked at the matter from an anatomical stand-point, while he regarded it mainly from a clinical stand-point. Although the name typho-malaria was of recent origin, this special form of disease had been recognized many years ago by Dr. Drake, who, in his great work on the diseases of the Mississippi Valley, had designated it as malario-typhus.

Dr. Hocheimer said that he was glad to inform the last speaker that the Board of Health was now engaged in the work which he had recommended, and that during the past season he himself (Dr. Hocheimer) had been among those whose duty it was to investigate the circumstances connected with every case of typhoid fever reported in the city. One of the special features which he had noted about the disease as it had prevailed of late was that the central portion of the city (between Sixth and Lexington Avenues) was almost entirely exempt from its ravages, while in the districts along the rivers, both east and west, by far the greatest number of cases occurred. When instances were found in the central district they could almost invariably be traced to a source out of town. It was also worthy of note that typhoid fever as now found in New York differed very greatly from the typical description of the text-books. In nine tenths of the cases not half the ordinary symptoms of the disease could be found.

In regard to some of the sanitary aspects of the disease that he had noticed, he went on to say that no case of it had been found in a house provided with the school sink unless the latter was in a filthy condition or out of repair. In houses with privy vaults it was met with where the vaults were not ventilated or where the ventilating pipes had traps. It was also interesting to note that cases of it occurred on the fourth floor of houses where there were houses in the rear, to the roofs of which the ventilating pipes were carried, these roofs being just on a level with the fourth floors of the houses in front. Where the premises were provided with water closets the cases of typhoid fever were generally found on the upper floors, where the water supply was imperfect and irregular. The youngest child that he had seen ill with it was twenty-two months old, and, as a rule, he found that young children were not attacked by it except after a comparatively long exposure to infection. The greatest number of cases occurred in persons between the ages of twelve and forty, while there was a remarkable immunity in those between forty and sixty. Persons over sixty, however, were found exceedingly liable to contact the disease.

In closing the discussion Dr. Janeway made a few remarks in regard to typho-malaria, the use of which term, he said, tended to keep physicians as well as patients from taking proper precautions in regard to the dejecta, which it was such an essential point to thoroughly disinfect in every case of typhoid fever whether there was any malarial complication or not. Therefore on this ground, as well as from anatomical considerations, he was opposed to the designation, and thought that in those cases in which it would seem to apply clinically it was better to speak of the malarial element simply as a complication of the typhoid fever.

SPECIMENS OF SARCOMA, ETC.

Dr. George L. Peabody presented a specimen of spindle-celled sarcoma of the dura mater, which, he said, was of interest as offering a negative contribution to the subject of cerebral localization, since, although its convex surface made a decided depression in the left hemisphere, its situation was out of the motor tract and no paralysis was caused by it. The patient was seventy-two years of age at the time of death, and as far as the history of the case could be ascertained there had been absolutely no symptoms referable to the tumor.

Dr. Gouley mentioned a somewhat similar case which he had reported in the first number of the *New York Medical Journal*, in 1864, and Dr. Flint then presented a rare and interesting specimen of congenital stenosis of the pulmonary artery, which had led to a reversal of the ordinary conditions in the heart, the right ventricle being relatively very large, and the left ventricle extremely small.

Dr. Janeway related a similar case which he had seen some years ago, after which the President, Dr. Detmold, made, by request, some remarks on the

DIAGNOSIS AND TREATMENT OF SYPHILIS.

All were aware, he said, of the difficulty which was sometimes met with in practice in deciding whether certain symptoms noticed were of specific origin or not, especially in instances where the patient denied ever having had syphilis, or was really unaware that such had been the case. It might, therefore, be of interest to know that there was one indication which he considered absolutely pathognomonic of syphilis, although the text-books seemed to attach little or no importance to it. He did not hesitate to say, however, that he had never in a single instance been misled by it. After referring to the predilection of different diseases for special tissues and organs, and instancing scrofula particularly, as prone to attack the cancellated structure of the bones, he went on to say that syphilis had a decided preference for the bodies of the bones, and especially those bones which were not covered by large masses of muscular or fibrous tissue. Among these might be mentioned the anterior aspect of the tibia, the surface of the ulna, the sternum, the bones of the nose, and the bones of the skull; but of all these the favorite seat of secondary syphilis in the bones was the anterior surface of the tibia. A chronic periostitis was set up, and, as an invariable result of this, there was œdema over the bone. The peculiar feature of this œdema was that it was permanent, so permanent that it continued throughout the rest of the patient's life. Hence this constituted an ineffaceable and certain sign of syphilis, and it was this to which he referred as a pathognomonic symptom. It was true, of course, that œdema over the tibia might be the result of injury, or other causes; but where this œdema was found in both legs, and no local cause could be assigned for it, there could be no reasonable doubt that the patient had had syphilis.

The treatment which he advocated, Dr. Detmold said, was different from that ordinarily recommended in the text-books and from that ordinarily resorted to in practice; but his experience had been so extremely satisfactory with it that he did not hesitate to recommend it to others. Some years ago he was called upon to treat a gentleman suffering from syphilis who had such

an intolerance of mercury given in any of the ordinary ways that it was constantly necessary to suspend its administration, and, consequently, it seemed almost impossible to secure a permanent cure. Under these circumstances he determined to try the external use of a solution of bichloride of mercury, and accordingly directed the patient to rub one grain of corrosive sublimate, dissolved in half an ounce of water, upon his body every night and morning; applying it to each of the extremities in turn. The results thus obtained were far beyond his expectations, and, in consequence of the marked success of the method, he had scarcely employed any other treatment since. It never produced salivation or other inconvenience of any importance, produced no local effect upon the skin, was perfectly clean, and, what was of more consequence, was efficient. Occasionally he thought he had seen it produce some griping pains in the stomach after it had been continued for some time, and in some cases it seemed to cause a slight discoloration of the finger-nails; which, however, he supposed was simply attributable to the friction to which they were exposed in the rubbing. On the whole, therefore, he preferred this method of administering mercury to any other, and he was glad to say that it had now been followed with success in various hospitals. If those present had never employed it, he thought it would be worth their while to give it a trial whenever occasion should offer.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, M. D., RECORDER.

THURSDAY evening, January 24, 1884, VICE-PRESIDENT SHAKESPEARE in the chair.

GENERAL TUBERCULOSIS OF SEROUS MEMBRANES.

Exhibited by DR. W. E. HUGHES.

Caroline K., white, aged seventeen, was admitted to the University Hospital November 3, 1883. There was a history of articular rheumatism in father and mother. The family was free from consumption. She herself had been perfectly well till eight months previous, when she developed symptoms of acute pleurisy. The acute symptoms subsided after a few days, and, with the exception of slight dyspnœa and hacking cough, she soon felt as well as before. Two months afterward she had pain, swelling, and redness involving successively all the large joints of the body, lasting ten weeks, and disappearing completely. From the onset of the articular symptoms her strength and flesh failed steadily, appetite grew poor, and digestion bad, dyspnœa and cough increased slightly. Five weeks before admission she began to have occasional sharp pains through the abdomen, and noticed that the abdomen was gradually enlarging. When first examined she was pale, somewhat emaciated, had hacking cough with mucous expectoration, slight constant dyspnœa, very little increased on exertion. The right pleural cavity was filled with fluid up to the third rib. The abdomen much distended with fluid free to move. The heart was normal in size, but there was a strong mitral systolic murmur. She had an irregular hectic fever. Under treatment the pleural effusion rapidly subsided, that in the abdomen less rapidly. One month after admission symptoms of meningitis developed, and examination of the eye-ground showed descending neuritis. A week afterward a double pericardial friction sound developed over the sternum opposite the third intercostal space. She died December 16th.

Autopsy seven hours after death. Thorax. Right pleural cavity completely obliterated by organized plastic adhesions. In the adhesions numerous gray miliary tubercles were found. Right lung congested, compressed, and contains scattered miliary tubercles. Left lung contains a few miliary tubercles. Pleura normal. Heart normal in size; marked thickening of mitral leaflets with incompetency. In the pericardium, at upper part of anterior surface of left auricle and over base of aorta, were a few small, grayish granulations, apparently tubercular. Peritoneal cavity contains about two quarts of straw-colored serum. Peritonæum everywhere thickly studded with gray miliary tubercles. Old peritoneal adhesions in several parts of abdomen, notably in left lumbar region and around pancreas. These old adhesions are filled with miliary tubercles. Lymphatic glands moderately enlarged, not cheesy. Numerous gray miliary tubercles in membranes of base of brain, especially in Sylvian fissures. No tubercles in any organs except the lungs.

TUBERCULAR ULCERS OF INTESTINES WITH PERFORATION.

Exhibited by DR. WILLIAM E. HUGHES.

William I., white, aged thirty, was admitted to the University Hospital April 16, 1883. His mother and a sister died of phthisis. He always took cold easily, and was never strong. Two years ago, after lifting a heavy weight, he had several slight pulmonary hæmorrhages. At that time he had no cough. Four months before admission he took a heavy cold. From that time up to his admission he had a dry, hacking cough with mucous expectoration, some dyspnœa, pleuritic pains on the right side, and a few small hæmorrhages. He lost twenty pounds. On admission there was in the lower part of the right pleural cavity an effusion localized in the posterior half. Over the right lung the respiration was somewhat roughened, with an occasional bronchitic rhonchus. The left lung was normal. Under treatment the effusion subsided, but consolidation commenced at the apex of the right lung. The consolidation went on to breaking down, and the same process commenced at the left apex. He gradually failed with the usual phthisical history. One month before death uncontrollable diarrhœa developed, with severe colicky pains and intense tenderness throughout the abdomen. He died December 26th of gradually increasing asthenia.

Autopsy three hours after death. Great emaciation. The right pleural cavity was completely obliterated by firm, old adhesions; on the left there were some adhesions at the apex; no fluid. The right lung had numerous small cavities in the apex; the lower two lobes were studded with miliary tubercles and small cheesy masses. The left lung was at the apex indurated with tubercular and cheesy deposits; in all other parts it was healthy; bronchial glands were enlarged. The heart weighed four and one half ounces. The aorta was slightly atheromatous. The liver weighed two and one half pounds, and was somewhat nutmeg in appearance. The spleen weighed two and two thirds ounces. The kidneys were normal in size and appearance. The intestines were everywhere adherent to each other and to the abdominal wall, and scattered through the adhesions and over the peritonæum were

a few miliary tubercles. The small intestine contained tubercular ulcers strung along its length from the lower part of the duodenum to the ileo-cæcal valve. They were about as numerous in the upper part of the intestine as in the lower. Several of these ulcers had perforated the peritoneal coat, but the contents of the intestine were prevented from exuding into the abdominal cavity by adhesions which had formed around the perforations to the neighboring peritoneal surfaces. There were a few tubercular ulcers in the colon. The mesenteric glands were enormously enlarged.

PHTHISIS FOLLOWING EMPYEMA; AMYLOID KIDNEYS; CANCER OF UTERUS.

Exhibited by Dr. William E. Hughes.

Amanda F., white, aged thirty-eight, was admitted to the University Hospital for cancer of the uterus. She had been a sewing woman, and had been much exposed to draughts. Her mother died of cancer of the uterus. There was no phthisical family history. One of her children died of tubercular meningitis. While in the hospital she complained of pulmonary symptoms, and physical examination of her lungs showed on the left posteriorly flatness down to midway between the spine and the angle of the scapula, with blowing, breathing, and gurgling râles, anteriorly tympany with metallic, cavernous breathing; at the base a small amount of fluid free to move. On the right hyper-resonance with exaggerated breathing, and at the apex moist râles. Her general condition was much below par. She had a troublesome loose cough, with free muco-purulent expectoration, and pleuritic pains through both sides of her chest. Five and a half years before she had taken a severe cold, from which she dated all her trouble. With the cold there had been severe pleuritic pain in the left side, some dyspnœa, and slight muco-purulent expectoration, occasionally streaked with blood. In a month she had lost twenty pounds. Afterward the acute symptoms disappeared, the pain grew less severe, the cough looser, and the expectoration quite profuse. She slowly lost ground till about a year before, when, after a succession of heavy colds, her condition deteriorated more rapidly. There was more dyspnœa, more cough, and an occasional rise of temperature preceded by chilliness. During this year she had several pulmonary hæmorrhages. For a month the frequency of micturition had been much increased, but the urine contained no albumen, though the quantity was increased and the specific gravity somewhat lowered. The first symptoms of cancer of the uterus had appeared about seven months before. For more than a month after admission she improved, then, a day after a rather profuse pulmonary hæmorrhage, she developed a typical uræmic condition. The urine was very scanty and loaded with albumen, but contained neither tube casts nor blood. The uræmic condition disappeared after two days, and the urine increased to its former quantity, all but a trace of the albumen disappearing. Two weeks after this, for the first time, a few waxy and epithelial casts were found in the urine. From this time on the quantity of urine passed daily varied from fifty ounces to seventy ounces, its specific gravity ranged between 1008 and 1015, and the quantity of albumen contained steadily increased till toward the end it became as much as one third of the bulk of the urine. At no time were very many tube casts present, though they were never absent they were either waxy or epithelial. She died January 1, 1884, of uræmia; which had gradually developed.

Autopsy five hours after death. Much emaciation. The left lung was compressed, atrophied, and firmly bound down in the posterior part of the pleural cavity. The remainder of the cavity contained gas and about eight ounces of sero-pus. The pleura was much thickened and transformed into a pyogenic membrane. The lung itself was hollowed out into a large cavity with suppurating walls by an extensive series of bronchial dilatations with more or less destruction of lung tissue. The lung was so torn in its removal that it was impossible to say whether or not there had been a communication between it and the pleural cavity. The right lung was emphysematous, and contained some tubercular and cheesy deposits at the apex. The heart weighed nine ounces, its right cavities contained an unusually developed ante-mortem clot closely moulded to the pulmonary valve. The kidneys weighed eleven and a half ounces, and presented very characteristic amyloid change. The body of the uterus was unchanged, but its cervix and the upper part of the vagina were destroyed by cancerous ulceration. There was no infiltration of the lymphatic glands. Other organs normal.

SECONDARY TUBERCULOSIS OF THE BLADDER, URETER, KIDNEY, AND SUPRARENAL BODY.

Exhibited by William E. Hughes, M. D.

Ida G., white, aged nineteen, had suffered with the usual symptoms of phthisis for about nine months before she came under observation. Her father and a sister had died of phthisis, and she had always taken cold on the slightest exposure. When first seen she was standing leaning over the back of a chair suffering the most agonizing pain in the region of the bladder. Desire to urinate was constant and irresistible, and the passage of the small quantities of urine gave rise to such suffering that she would shriek and almost faint. Till two weeks previous there had been no trouble with the urine, then the pain began, slight at first, and became gradually more and more severe. She had passed frequently masses of clotted blood with great suffering. Under anodynes the pain became less, and an examination of the bladder showed it to be much contracted with roughened walls. Examination also brought on a slight hæmorrhage. The urine contained nothing abnormal except blood and pus. Under the continued use of anodynes the pain decreased and finally disappeared. After the cessation of pain the blood disappeared from the urine, but was replaced about two months afterward by a small quantity of albumen and a few granular tube casts. About this time œdema began in the ankles and gradually involved the whole of the lower extremities. The tissues finally became so distended that her legs were utterly useless. The urine never contained more than one tenth of its bulk of albumen, and the tube casts were always few in number. She died of asthenia four months after coming under observation.

Autopsy fourteen hours after death. Extensive degeneration of lungs. Liver was extremely fatty, being of a uniformly yellow color with no distinction whatever between its lobules. The bladder was small and firmly contracted, its walls thickened, its inner surface roughened, rugose, papillomatous, its mucous membrane thickly studded with tubercle granulations. The substance of the right kidney contained numerous gray miliary tubercles, its pelvis was dilated and presenting

the same appearance as the inner surface of the bladder. The corresponding ureter was as thick as an index finger, its walls firm, hard, infiltrated with tubercular deposit, its mucous membrane in the same condition as that of the pelvis of the kidney. The right suprarenal body retained none of its original structure, it was a mass of cheesy tubercles firmly adherent to the kidney. The left kidney, as well as the other organs, was normal.

DR. FORMAD had examined these specimens for bacilli. None were found in the first case although the post mortem was made within about two hours after death and frozen sections at once cut. The lymph glands were also examined as well as the lungs without detecting any bacilli. In Dr. Hughes's second case the lymph glands as well as the perivascular spaces were crowded with colonies of bacilli. In the first case was an absolutely primary tuberculosis of the serous membranes with no bacilli, while in the second, *ulceration* was present with lymph gland bacilli as well as invasion of other tissues. This would indicate that bacilli and general tuberculosis most commonly result from surface troubles, that is, the mucous membrane of the lungs, intestines, etc., when affected by tuberculosis. In the case of tuberculosis of the serous membranes there was no history of a strumous diathesis, and no general tuberculosis ensued. From the careful study of ten similar cases Dr. Formad was inclined to think that serous tuberculosis was the only form of the disease to which *non strumous* individuals were liable.

DR. SHAKESPEARE said that he had been struck with the fact that the third case, with a family history of carcinoma, apparently developed tuberculosis after empyema, and that, post mortem, carcinoma of the uterus was found. An antagonism between these two diseases has been long believed in, but of late has been questioned, since a careful scrutiny of statistics has shown them to be more commonly associated than is generally believed. Dr. Shakespeare then called attention to the fact that in most cases a family history was obtained running back for only one generation, yet, there being no statement as to what degree the investigations had been carried, statistics drawn from such sources must be unreliable, as Dr. Formad, among others, has called attention to the fact that tuberculosis can and often *does* skip one generation. There were some points in the history of the case of tuberculosis of the serous membranes which suggested that the primary trouble might have arisen in the joints which are closely analogous to serous sacs, if they are not actually such.

DR. HUGHES said that in the patient where he had stated that the family history was good, he had gone back for three generations, directly and collaterally.

DR. MUSSER asked what was the effect of repeated tappings on the development of tubercle, as some clinical teachers are now advising against such operations in simple pleurisies, advocating in preference other remedies to induce rapid absorption of the effusion.

DR. J. C. WILSON thought this question could only be answered by an analysis of a large number of cases specially examined for this purpose.

DR. SHAKESPEARE having been informed by Dr. Hughes that the so-called tubercles in the case of carcinoma had not been examined microscopically suggested the reference of this specimen to the Committee on Morbid Growths, since it might really be only a case of miliary carcinosis and not tubercle. With reference to the influence of tapping on the development of tubercle the latter seemed to be most frequently developed where no tapping had been performed, but where rapid resorption had taken place. Pathological experiment has shown with what ease any innocuous substance, even simple traumatisms, will set up tuberculosis of the serous membranes. If, then, a general tuberculosis can result from tubercle of serous membranes — a point not settled as yet by experimenters — repeated tappings, with perhaps the coincident introduction of deleterious substances, might account for the alleged fact mentioned by Dr. Musser.

TUMOR OF THE ANTERIOR MEDIASTINUM WITH SECONDARY DEPOSITS IN THE HEART AND LUNGS.

Presented by DR. J. C. WILSON.

The specimens were removed from the body of an unmarried woman, aged sixty years, who died in the hospital of the Jefferson College, January 7, 1884. The patient had been singularly free from sickness until about eighteen months before coming to the hospital, three weeks prior to her death. The earliest symptoms were fixed pains of varying intensity in the sternal region, with attacks of palpitation and dyspnœa. These symptoms increased in severity, and were aggravated by exertion. After a time she began to experience difficulty in swallowing. Six weeks before admission to the hospital her feet and legs were for the first time observed to be swollen. The dropsy soon became general. She had no knowledge of her family history. On admission she suffered from constant dyspnœa, paroxysmal, often urgent, worse at night; inability to lie down; occasional unproductive cough; a sense of weight and oppression in the chest, and particularly in the precordial region; pain under the sternum; and great discomfort in swallowing. There was a high degree of general anasarca, and the evidences of pleural and peritoneal effusion. The surface was cool, the skin bluish. The examination of the chest was rendered difficult by the unusual thickness of the tissues, the patient being not only enormously dropsical, but also very fat, and the breasts being hugely developed. It was nevertheless noted that the impulse of the heart was feebly felt, the apex beating in the sixth interspace, and somewhat to the left of its usual position; that a faint systolic blowing murmur was heard at the apex, feebly propagated towards the left; that the heart sounds at the base were unusually obscure; and that the pulse was feeble, frequent, and irregular. There was flatness with absence of respiratory murmur at the base of the chest on both sides, and harsh, broncho-vesicular respiration over the upper regions of the chest. In the upper sternal region the cutaneous venous tinge was conspicuous without rising, as is sometimes seen, above the level of the skin. The veins were dilated and tortuous, and symmetrically arranged beyond the sternal borders, at which they abruptly ceased. The thyroid body was enlarged, and formed an egg-like projection in the median line. It was exceeding hard, but not sensitive nor the seat of pain. The patient regarded it with indifference, and said that *the lump* had existed for "many years."

I was, unfortunately, prevented from being present at the necropsy, and this tumor was not removed.

The boundaries of dullness in the pericardium could not be distinctly made out. It was, however, noted that the distribution of percussion signs absolutely negatived the existence of aneurism of the aortic arch as

their cause. The pupils were equal in size, and in response to light. The voice was unchanged. The radial pulses equal.

The patient died suddenly in an attack of dyspnœa at nine P. M. on the 7th of January.

Necropsy. Body much swollen and œdematous. Face and thorax very blue. Both the pleural sacs and the peritoneal cavity contained fluid in large amounts. Strong pleural adhesions on left side. The anterior mediastinum in its upper segment was occupied by a large, firm mass, mammilated in structure, extending from the notch of the sternum downwards for five inches, and adherent to the lung and the costal cartilages. The width was about three inches, and its depth, in an antero-posterior direction, about the same. It occupied exactly the position of the thymus gland. Its visceral surface was embossed, but smooth, and in its upper portions only adherent to the great vessels. No adhesions existed between the parietal pericardium covering its posterior surface and the visceral layer of the pericardium.

Recent Literature.

On Sterility in Woman. By J. MATTHEWS DUNCAN, M. D., LL.D. Philadelphia: P. Blakiston, Son & Co. 1884.

This book is a reprint of the Gulstonian Lectures delivered by Duncan in the Royal College of Physicians, London, in February, 1883. As the author says in his preface, "they form a mere outline sketch of the parts of the subject of which they treat"; yet they are sufficiently comprehensive to give the reader a clear idea of the subject as at present understood, and are replete with statistics and suggestions that will aid the student in further investigations.

The subject is treated under three heads: Nature and Amount, Theory or Causation, and Prevention and Cure. At the outset the author excludes from consideration those cases where conception is impossible on account of such causes as absence of the uterus or imperforation of the vagina. He then defines his subject under the heads of absolute sterility, where there is no conception, or where the impregnated ovum is lost without leading to what is recognizable as an early abortion; and of sterility not absolute, by which he means the failure to produce a viable child, while there is evidence of conception. He also deals with the condition known as relative or acquired sterility, by which is meant the failure to produce in number according to the conditions of age and length of married life, even though the woman may have borne one or more living children.

Under the head of Theory or Causation the author considers analogous conditions in vegetable and animal life, showing in what way fertility is affected by circumstances of heat and cold, over- or under-feeding, youth and old age, confinement and domestication. He points out the fact that plants frequently produce seeds apparently perfect, but which will not germinate; also that fowls produce eggs that will not hatch, although affording no evident imperfection: "that there are such ova in other animals and in women is highly probable; but in them the completeness of the demonstration is unattainable." The variations of sterility in woman according to the age at marriage is dwelt upon at some length, and the conclusion drawn that premature marriage is a cause of sterility. The causes of the comparative infertility of heiresses and the wives of peers are touched upon; and the allies of sterility, excessive production, pluriparity, and abortion receive adequate attention. Dysmenorrhœa, so frequently associated with sterility, especially the spasmodic variety, and other neurotic conditions, such as depraved or absent sexual appetite and pleasure, and so-called dyspareunia, are fully considered.

So far as the prevention of sterility is concerned, the author believes the best hopes of success lie in the avoidance of unions with immature or post-mature women, that is with women under twenty or over twenty-five, as he has shown the period between those extremes to be the best marriageable age with a view to fertility and the rearing of healthy children and the safety of the mothers: this prevention can of course only be attained by the diffusion of knowledge as to the probabilities of fertility according to the age at which marriage is entered upon. Under existing conditions of society, however, not much is to be hoped for in this direction; and certainly so far as the practical physician is concerned he must take things as he finds them and devote his attention to the search for, and removal of, other causes of sterility than those of age. In a certain proportion of cases the dysmenorrhœa, which is frequently the concomitant of sterility, may be found to be due to mechanical obstruction: in a certain other proportion intra-uterine or para-metric disease may be the cause upon which the sterility depends. But the author believes that local causes cover but a small proportion of the cases of sterility, and that the cure of the sterile condition is to be sought in the improvement of the general health and attention to the nutrition and hygiene of individual cases.

As a whole the book is not one which will commend itself to the mechanically disposed gynæcologist; but to the general physician and the medical economist we believe it will prove instructive and interesting.

C. M. G.

The Diagnosis of Diseases of the Spinal Cord. By W. R. GOWERS. Third Edition. Philadelphia: P. Blakiston, Son & Co. 1884.

Dr. Gowers has resisted any temptation to unduly increase the size of his book; it is the same compact, satisfactory little treatise in the third edition that it was in the earlier, and is well worth reading. A few symptoms have been considered a little more in detail; a section has been added in regard to the distinction of functional and organic disease.

The excess of "myotatic contractions" (the deep reflexes), which are found in cases of degeneration of the pyramidal tracts, are referred to changes in the gray substance of the cord in which the fibres of the pyramidal tracts are lost in its interlacing net-work of fine fibres and minute nerve cells. "The phenomena are best explained by the hypothesis that this structure, in the matrix of the gray matter, controls the muscle-reflex centres (of which the ganglion cells are part), and that the degeneration of the pyramidal fibres, which can be traced to the gray matter, invades this structure."

Medical and Surgical Journal.

THURSDAY, FEBRUARY 28, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE METRIC SYSTEM AND THE PYRAMID OF GHIZEH.

As an example of a style of argument which is not infrequently brought to bear upon scientific questions we have been interested in a periodical which has just been launched upon the sea of journalism, and which is, in its own words, "a magazine devoted to the Preservation and Perfection of the Anglo-Saxon Weights and Measures and the Discussion and Dissemination of the Wisdom contained in the Great Pyramid of Jeezeh in Egypt." A model of the pyramid was displayed at the Foreign Exhibition in this city last fall, illustrating the peculiar theories of this Society. It is, in fact, to this ancient structure that the inch and the pound are to be ascribed. Though the cause is old the Society is new. It dates back, we are told, "only to noon of the eighth day of November, 1879, when at the Old South Church, Boston — that spot of wonderful memories and more wonderful prediction — we asked the blessing of God upon our undertaking, and the guidance of His Holy Spirit through the merits of His Son."

Of the ordinary arguments against the metric system this periodical makes not much account, save to say, for instance, that the value of the metre, 39.37 inches in length, is "a very awkward number," and that the metric system is "utterly deficient in availability" for the more comprehensive measures of the English system, in that it affords no separate table for liquids and solids, for surveyors', linear, and cloth measure. On other questions, such as the relative convenience of a decimal subdivision and of one into halves, quarters, etc., and the expense in time and money of putting the foreign system into use, there is room for diversity of opinion among sincere and honest men, and on them one may hear the pros and cons in every-day life. The Institute has a higher sphere. Its method is transcendental. The pith and marrow of the controversy is in the insidious attempt of the French and other European nations to subvert our Anglo-Saxon institutions and to foist upon us a "unit of measure born of infidelity and atheism in 1792." Shall we sell our birthright for a kilo of pottage? Never. It is not only on patriotic and ethnic but on religious grounds that we must resist the aggression of the corrupt despotisms of the Old World.

Have we not the divine command, "A just weight and a just measure shall ye have"? "Could the prophets of the Lord," asks the President of this Society in his inaugural address, "have so earnestly and so persistently declared for a just balance and a just measure if the origin of these was the result of *accident* or *caprice?*"

There being then a divinely appointed standard of measure, opposed to this wicked product of the French Revolution, it must be the Anglo-Saxon standard. Where can we find the original measure of that system? Obviously in that "venerable and stupendous monument which was erected, as we believe, for 'an Altar to the Lord in the midst of the land of Egypt and a Pillar at the border thereof to the Lord.' Isaiah, xix. 19." *Videlicet* the great pyramid of Jeezeh (Ghizeh). This is no problem fit for nineteenth century science. Go back to the time of Cheops and the fourth dynasty. Let no such question be discussed by the buyers and sellers of England and America. *Abeste profani.* On the sands of Egypt and beneath the everlasting smile of the Sphynx should its solution be sought. *The architect of the great pyramid used the British inch!* The diameter of the length of the granite floor of the king's chamber, the length of the king's chamber, and its diagonal diameter in inches multiplied by π all give integral numbers. The Anglo-Saxon inch is the talisman by which the circle can be squared! Elaborate mathematical formulæ involving the parallax of the sun (the diameter of the latter body, by the way, being given as 10″ less than the mean of all the best observations hitherto made) demonstrate that the inch is exactly one five-hundred-millionth of the polar diameter of the earth (said polar diameter being rather more than seven miles less than that accepted by practical astronomers). The fact that another mathematical contributor to the journal claims that the pyramid inch was $\frac{1}{989}$ greater than the British, and elsewhere asserts that the mysterious relations with π claimed for the standard inch are equally true for other values of the inch, seems in the mind of a layman to slightly weaken the force of the argument. But still it remains true, at least, that all accessible dimensions of the pyramid are capable of mensuration with the British yard-stick, and that fact can probably always be maintained against all cavil.

Not only does the pyramid give us our inch but our thermometric scale. Thus: The king's chamber begins at the fiftieth course of masonry. Hence the temperature of this room shall be 50° of the new scale. This corresponded on the occasion observed to 68° F. (or else should do so, from its being a perfect room, — the exact fact does not appear). Wherefore 250° Pyramid represents the boiling point of water. Thermometers on this scale have been constructed for the Society, and their general introduction is recommended. The centigrade scale, which savors of the abominable thing, is thus avoided. The Institute also proposes to take the meridian of the great pyramid as the zero point in its system of standard time.

On these vital grounds the International Institute sets out in its warfare on the metre. The adoption of this unit by the custom houses, marine hospitals, and coast survey fill it with undisguised alarm. The rec-

ognition of the metre by Congress is a usurpation. The Constitution authorizes it possibly to make changes in the system of weights and measures, but never to abolish the units. It is the duty of the "loyal and faithful citizen" to maintain a ceaseless vigil against that movement which, emanating from France, and sustained by the influence of Germany, Italy, Spain, Turkey, Egypt, Austria, Norway, and Sweden, is directed against the Anglo-Saxon world.

THE DETERMINATION OF SEX AT WILL.

SEVERAL years ago the JOURNAL[1] gave some account of the experiments of a gentleman named Fiquet upon a Texan cattle ranche in regard to the production of a desired sex at will, and the results at which he had arrived, with a somewhat limited experience, it is true, were detailed. He was enabled to predict the sex of calves in a dozen successive cases by preparing the bull and cow before coming together, the physiological hypothesis upon which he acted being that the sex would be the opposite of that of the more vigorous and eager progenitor. Mr. Fiquet reported that he had by experiments eliminated other theories as fallacious, and had finally been led to adopt this one and put it to practical tests by observations upon mankind.

Since then we have heard nothing more from Texas upon this subject, but singularly enough we get a large volume from London devoted to the elaboration of this principle, which applied to animals who can be selected and attuned to a given occasion with a chosen mate at a designated moment seems tolerably simple, although still hypothetical, but when extended to man becomes complex enough.

The writer of this octavo[2] of nearly three hundred pages on the Law of Sex states that he has spent twenty years of his life in studying the subject and its connected literature in various languages, and although his theory has been matured for several years its publication has been delayed until, by extensive observation, he "could establish its truth beyond the possibility of a doubt." This he evidently believes he has succeeded in doing so satisfactorily that he begins his preface with this sentence: "In the following pages I claim to make known a new discovery of a great law of Nature; nothing less than the law which governs the sexes, and whereby the sex of offspring can be controlled."

The "determination of sex" is almost as enticing to the average physiologist as the location of a new gold field to the average adventurer or the discovery of the philosopher's stone to the nearly extinct alchemist. The secret of making boys or girls at will is about as alluring as that of making gold or silver, or would be except in those places where it has been discovered by the sociologists that there is really very little difference between the sexes, and that such thinkers should care whether a given individual be a boy or a girl, though caring much whether it be a "radical or conservative," we, of course, do not believe. Still retaining ourselves, however, some of the old-fashioned ideas as to the distinct mission of the two sexes in the world's work, we have not lost our interest in the attempts, which from time to time get themselves into print, to evolve a law for the determination of sex at will, and in spite of the many preceding false starts are always ready to follow a new trail, especially when marked by a very promising sign-board indicating with confidence and precision a sure arrival at the heart of the mystery.

Hence we read undaunted through the first five chapters, or ninety pages, which are mainly devoted to setting forth the fallacies of previous and current theories, and reached with eagerness the sixth chapter which opens with the announcement that sex is determined by what the writer designates as the "superior parent;" also that the "superior" parent produces the opposite sex. This statement merely substituted a word we did not know how to interpret for everything else we did not understand. The author, apparently anticipating such a frame of mind on the part of the reader, apologizes for the expression as open to objections, but though not finding it entirely satisfactory still it is the best he could think of to express his meaning, which we prefer that he should assume the responsibility of making clear in his own words, as follows: "My difficulty in selecting a suitable designation for the controlling power in each case will be understood, when I state that among the numerous factors to be taken into account are the temperament, activity, energy, will, intellect, features, color, physique, bodily health, nutrition, etc., etc. The term 'superiority' will be used, but it must be understood to include all these, and to be susceptible of variation through temporary circumstances, — state of health, age, and the like; while the term '*inferiority*' will signify the opposite. The temperament and energy will be the more permanent elements of 'superiority;' but the invidious meaning of the word in ordinary social phraseology must be *altogether eliminated*. Let it be distinctly understood that '*superiority*' *here means everything that tends to increase functional energy* in any part of the system, and thus to influence the determination of sex; and it does not follow that this kind of 'superiority' must in all cases coincide with superiority in the general sense of the term — by which we imply superior mental and moral qualities. It may and often does happen that the two kinds of superiority are found together, but the coincidence is not necessary, and they are often, in fact, separated."

A little farther on we find: "Life, then, with all its phases must be the basis upon which to estimate 'superiority.'" And again: "*Cerebral development* is the key to *superiority* as understood in this work."

We did read the rest of Mr. Starkweather's book, but with a much diminished enthusiasm, and, as we carried with us a very vague comprehension of the

[1] Vol. cii., p. 471.

[2] The Law of Sex: Being an Exposition of the Natural Law by which the Sex of Offspring is Controlled in Man and the Lower Animals. And giving the Solution of Various Social Problems. With Forty Illustrative Portraits. By George B. Starkweather, F. R. G. S. London: J. & A. Churchill. 1883.

just interpretation of his word "superior," it is very probable under disadvantages. The "superior" bull of Mr. Fiquet was a comparatively simple creature; more food and better food, and a suitable seclusion, gave him the necessary advantage over a mate subjected to opposite conditions. The "superior" man, as previously described, is a very complex organism, which does not reveal itself so easily, and is not convenient to deal with when found.

We are not indisposed, in spite of our conservatism, to lend some credence to the statement that a "superior" father begets daughters, and are willing to regard a man, on the *post hoc propter hoc* principle, as "superior" because he has begotten daughters, and to extend the same, in strict impartiality, to mothers and sons; beyond this Mr. Starkweather has not succeeded in enlightening us with anything promising practical results. Other readers may be more fortunate, and for their encouragement we may state that, if the stamp of "superiority" is only recognized in the result of cohabitation, hopes are still held out that by a well considered lowering or elevation of the physical, mental, and moral tone (*morale*) on the one side and the other the mistake may still be corrected.

Where the temperamental equality of the parents is close slight causes will, of course, influence the sex of the offspring.[1] And time makes all things even, for the "superior" fathers of one generation transform themselves into the "superior" daughters and mothers of the next, and thus kindly Nature, even should we rob her of this mystery, will continue to balance her accounts and populate the earth.

MEDICAL NOTES.

— According to the *Révue Médicale*, M. Aimée Girard lately proposed at the Académie des Sciences the destruction of the bodies of animals dying of virulent diseases by means of sulphuric acid (as their interment does not always secure from the danger of contagion). M. Régnard thereupon resolved to try the effect of this substance on the human subject. His experiments with the bodies of new-born infants and fœtuses have been completely successful, and he believes would be equally so if tried on the adult. To the body of an infant he added about double its weight of the sulphuric acid of commerce, and after twenty-four or thirty hours of maceration not a vestige of the body remained, the decomposition having taken place silently and without any smell. Neither the microscope nor the test tube can detect the slightest trace of the body beyond the presence of some fat, phosphoric acid, and nitrogen. M. Régnard points out how easily a body may be made away with by means of a substance so easily procured, and suggests that some restrictions should be placed on its sale.

— In Manchester, Eng., a druggist dispensed "three pennyworth of quicksilver and three pennyworth of aqua fortis" to a man who wished to mix them to make some sort of an ointment. The man had bought these articles before, but they had always been put up separately. On this occasion they were put in the same bottle, which the man placed in his breast pocket, and left the shop. Very soon the bottle exploded, burning his face and eyes so seriously that he died at the Manchester Eye Hospital.

— The Senate of the United States has recently voted to recompense Surgeon E. P. Vollum, of the army, for the loss of his personal effects sustained by shipwreck while in the line of duty in the year 1856. The amount awarded is $700.

— Bermingham & Co., medical publishers, of 28 Union Square, who made an assignment on the 19th ult., have resumed business, the temporary embarrassment which caused the assignment having been removed, and the assignee having reassigned to said firm.

NEW YORK.

— A committee representing the Association for Improving the Condition of the Poor, one of the members of which was Dr. F. R. Sturgis, had a conference, on the 21st of February, with General Shaler and Dr. Woolsey Johnson, of the Health Department, with reference to the condition of the tenement houses of the city, the principal subject discussed being the insufficient water supply now existing in many of the houses, with its attendant uncleanliness and increased risk of disease. The committee also called the attention of the Health Commissioners to the fact that the law which requires the name of the owner or agent of every house inhabited by three or more families to be posted in the entrance had become a dead letter, and General Shaler assured them that if it was within the province of the Health Department to cause it to be done the law would be strictly enforced in the future.

— The German Society of the City of New York, which this year celebrates its centennial anniversary, has just published its annual report, prefacing it with some account of its history during the past hundred years. Among the institutions which it has been instrumental in founding are the German Hospital and Dispensary, and the report urges the necessity at the present time of a hospital for convalescents and incurables.

— The first annual report of the New York Skin and Cancer Hospital has just been published. In it the following figures in reference to the increasing mortality from cancer in New York City are given: In 1869 there were 304 deaths from cancer, being a little over one per hundred of deaths from all causes. In 1879 there were 572 deaths from cancer, or a trifle over two per hundred of all deaths, that is, in ten years the proportion of deaths from cancer had nearly doubled. In 1880 there were 659 deaths from cancer, or 2.06 per cent. of all deaths, the mortality from the disease being greater than that from scarlet fever, which amounted to 618. In 1881 cancer caused 707 deaths, and in 1882 731 deaths, while during the fourteen years mentioned there were 6843 deaths

[1] A convenient head under which to classify numerous exceptions to the law.

from it. Up to the time of the establishment of this hospital cancer patients were admitted to only one or two institutions in the city, and then not for the purpose of treatment, but simply to await the fatal termination of the disease, and nowhere in this country had cancer cases been grouped together with a view of studying the disease as to its nature and cure. The dispensary department of the hospital was opened on the 11th of January, 1883, and from that date to December 31st 767 patients were entered on the books, who made altogether 2708 visits. On the 24th of February a ward, with five beds for female patients, was opened, and afterwards twenty-nine beds were fitted up in the building, which is situated in Thirty-Fourth Street, between Second and Third Avenues. Five of these are reserved for males, and three for children. The total number of patients treated in the wards was seventy-six. The great need of the institution at the present time is for a country branch hospital, where chronic and offensive cases can be treated in small pavilion buildings, and a subscription toward this purpose has been started. It is hoped by this means to be able to receive any and every case of cancer needing hospital assistance, and in the end to have this department one of great magnitude and importance. Appropriate cases of skin disease would also be transferred to the country branch as circumstances required. During the year forty-nine cases of cancer (including sarcoma and epithelioma) were treated, of whom thirty-seven were females and twelve males. Among the other cases treated were one of elephantiasis Arabum, two of hydroa, one of keloid, two of leucoderma, and one of true leprosy. On the medical staff the principal physicians are Drs. L. Duncan Bulkley and George H. Fox, gynæcologist, Dr. James B. Hunter, and operating surgeons, Drs. Robert F. Weir and Edward L. Keyes.

— St. John's School at Manlius, New York, has been closed on account of the prevalence of diphtheria among the scholars.

Correspondence.

HARTZELL'S METHOD FOR STAINING THE TUBERCLE BACILLUS.

MR. EDITOR, — In your issue for February 14, 1884, you quote Dr. Hartzell's method for staining the tubercle bacillus, which he claims to be new, and to have the advantage over other methods of avoiding the use of nitric acid as the decolorizing agent. The latter is of course true; but at the same time that we get rid of the nitric acid we lose the *diagnostic* value of the Ehrlich method. This is proven by experiments which I have made with Dr. Hartzell's method in the last fortnight, using it exactly as he directs upon half a dozen distinct forms of micro-organisms. I find that they are all stained equally well by this method as is the tubercle bacillus. Therefore the method is only of value as an indication of the presence of micro-organisms in general, and should certainly not be relied upon for the diagnosis of any special form.

Dr. Gradle, using the same method of staining with the substitution of nitric acid for the oxalic acid recommended by Dr. Hartzell, says: "I found in most sputa a micrococcus in chains, and a bacillus a trifle longer and much thicker than the real tubercle bacilli. The latter, however, are stained much darker, and can be recognized besides by their size and shape. While, therefore, this method enables us to decide instantly whether the sought-for bacilli are absent in a sputum, any doubt as to their identity in case of their presence may be removed by the use of the more characteristic aniline method." [1]

The hope of preventing any more confusion by the adoption of faulty methods in the investigation of this subject must serve as my excuse for trespassing upon your space. Very truly yours,

HAROLD C. ERNST, M. D.

JAMAICA PLAIN, *February* 23, 1884.

Miscellany.

THE GOVERNMENT CONTROL OF THE UNITED STATES PHARMACOPŒIA.

THE *North Carolina Medical Journal* for February publishes the following excellent editorial on this subject: —

A bill has been introduced into the House of Representatives, by Mr. Randall, of Pennsylvania, to prepare and publish a national pharmacopœia. The chief of the Marine Hospital Service, of the Navy, and of the Army are each to detail two medical officers, and these officers are to invite the American Medical Association and the American Pharmaceutical Association to form committees of not more than three members, and thus constituted this board shall proceed to the work of forming a new pharmacopœia, said board having the power to add to its number from time to time as may in its judgment be necessary. Five thousand dollars are to be appropriated for carrying out the work.

No doubt this proposition will strike the profession in this country with surprise, more especially when the history of the Pharmacopœia is recalled. From the beginning the labor and expense of the production of this work has been undertaken and carried forward by enterprise. The few men who have been interested in it have given their time and labor with an ardor which does credit to the two professions from which they came. Furthermore, they had the wisdom to keep this work alive by their desire to promote the best interest of the profession, and we are quite sure that none would have resisted quicker than they any movement, even by implication, which would have surrendered the work to the general government. This is more than ever inferable when we remember, that in the early conventions the organization was completed before the officers of the army and navy were invited to take seats.

It will be surprising, therefore, to the profession, that there should have suddenly arisen an emergency which makes it now more necessary that "a national authorative standard" should be undertaken by the government.

The *Medical News*, it seems, is able to give a reason. In its issue of 9th February it says: "Unfortunately, since 1880 the United States Pharmacopœia has be-

[1] Bacteria and the Germ Theory of Disease, page 166.

come a matter of commercial speculation. While a vast amount of intelligent and well-directed labor was bestowed upon it by the Committee of Revision, taken as a whole it is by no means creditable to the science of the country, and complaints as to its inaccurary and the inconvenience of its methods have been numerous. Not only was it thus inferior to former revisions, but it was padded out into an absurdly large and clumsy volume, and supplied to the profession at an extravagant price wholly disproportionate to its former rate. That this departure from the time-honored course followed in former revisions should awaken widespread dissatisfaction was inevitable; and it was to be anticipated that the dissatisfaction would lead the government to supply a want which had always existed, but which had never before become so imperative as now."

Per contra, we consider it rather fortunate that the committee has been able to produce a volume that could attain to any sort of a commercial dignity instead of preparing revision after revision that did not possess any. We cannot agree either that the revision was supplied at an extravagant price, for had this been so the volume would not have been sought after so eagerly in the book market by such a large number of purchasers, a number far greater than for any previous edition however cheap. The medical and pharmaceutical professions were willing to pay the price asked for the work, just as they would for anything they thought worth the money.

As to the inferiority of the present revision as compared with previous ones, we will let the *British Medical Journal*, page 700 (October 1883) speak. The reviewer in that journal has been comparing the British Pharmacopœia, the German Pharmacopœia, and the United States Pharmacopœia (1880) and says: "In comparing the three Pharmacopœias, it must at once be conceded that the United States Pharmacopœia is incomparably the best. The previous revision was very poor, but the present revision is a very great improvement on the last. It contains an enormous mass of information, which is, however, chiefly of use to the pharmacist. Nevertheless it contains almost every possible preparation which can be needed by the medical practitioner."

We think the *Medical News* will be greatly disappointed in not finding "professional approval" [of the proposed National Pharmacopœia] "practically unanimous." Not a large number of men are going to give the matter a thought, if we are to judge by the past. But of those who do actively consider the subject, we believe that very few will have such poor memories as to overlook the undesirable basis upon which, by the conditions of this bill, the national pharmacopœia would be founded. An expensive and disappointing experiment has already been tried by attempting to combine such incongruous bodies as the Army, Navy, and Marine Hospital Service, and the result was the wrecking of the National Board of Health, through the ambition of the Marine Hospital Service. With this disaster staring a confiding profession in the face, it is now proposed to reform the old combination, and to attach enough civilian experts to the board to give it a general scientific character, and so avoid the suspicion of making it a purely government work.

We think when these facts are duly considered, if the profession of medicine and pharmacy are to have any voice in the matter, they will more nearly unanimously reject the proposition.

Another point. The whole movement as set forth first in the Randall Bill, and in the approving editorial of the *Medical News*, has too much of the color of rivalry between New York and Philadelphia not to be understood by non-residents of those favored cities. Some of the gentlemen of the latter city have never been able to disguise their dissatisfaction at the departure of the Pharmacopœia from them, and we do not believe a word of complaint against the scientific part of the present revision of the Pharmacopœia would have been sounded had the business management been to the liking of the complainants.

But we assert, even if the proposed plan is excellent in every respect, there is no reason why a new Pharmacopœia should be compiled at an earlier date than 1890. We are willing to take the opinion of the *British Medical Journal* upon this subject, and repeat that the U. S. Pharmacopœia is incomparably the best in any language, and a wise Congress will not willingly interrupt the course of a scientific body, pursuing its work zealously and honestly, and at its *own expense*.

THE GRANT OF £10,000 TO THE PHYSIOLOGICAL LABORATORY OF OXFORD CONSIDERED AS A "NATIONAL DISASTER."

AFTER two pages of print devoted to various woes and horrors of the preceding week, among which appears a statement of the slaughter of twenty-three hundred Egyptian soldiers and eighteen European officers, the *Spectator* of February 9th exhibits the following paragraphs, which, if found in anything except an anti-vivisection organ, would be mildly characterized as amazingly silly: —

"Not the least of the disasters of the week — if we look at it from the point of view of the principle involved, — is the carrying in the Oxford Convocation on Tuesday of the decree voting £10,000 to the physiological laboratory at Oxford, without any sort of restriction on the vivisectional experiments which — for the purposes of research — may be carried on there. The Dean of Christ church proposed the decree, expressing the most perfect confidence in the kindness and humanity of Professor Sanderson, — a confidence which will be present or absent, according to what is understood by kindness and humanity, and that is precisely the matter in dispute. Mr. Freeman, the historian, made a very masterly speech, showing that the students and teachers of all branches of knowledge were understood to pursue these subjects under those general restrictions involved in refraining from using blameworthy means. You might revive gladiatorial shows or bull-baiting, he said, to throw a new light on history, but any one who did so would be severely condemned. Only in the case of physiology was a vote of money proposed such as could never have been got out of the University for such an object as the new School of Art at Athens, in order to foster a method of research which did not scruple to do what for any other purpose all men would condemn.

"The other speakers were chiefly favorable to the vote. The Warden of Keble surprised and grieved a great many of his friends by deprecating at this stage resistance to the vote. Professor Acland, in the silky accents familiar to the University, dilated, in what has been termed a 'beautiful speech,' on the thesis that

nothing more directly conducive to the cause of humanity has ever been conceived than the vivisectional method of investigation, and no doubt he may have convinced some of his more innocent hearers that, in the interests of the dumb creation, they should at once put themselves in training for bland and loving acts of vivisection. Dr. Pope made a not very judicious speech on the other side, and then the decree was carried by one hundred and eighty-eight votes against one hundred and forty-seven; majority, forty-one."

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 16, 1884.

Deaths reported 2164: under five years of age, 796: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 377, lung diseases 365, consumption 333, diphtheria and croup 141, scarlet fever 65, diarrhœal diseases 38, typhoid fever 35, measles 30, cerebro-spinal meningitis 23, malarial fevers 15, erysipelas 13, whooping-cough 10, puerperal fever seven, small-pox three. From *diarrhœal diseases*, New York 15, Boston 11, St. Louis four, Chicago, Baltimore, and Buffalo two each, Providence and Haverhill one each. From *measles*, New York 12, Baltimore 11, Philadelphia four, New Haven two, St. Louis one. From *cerebro-spinal meningitis*, New York eight, Chicago three, Philadelphia and Milwaukee two each, Baltimore, Buffalo, New Haven, Lawrence, and Salem one each. From *malarial fevers*, New York nine, Baltimore four, St. Louis two. From *erysipelas*, New York five, Philadelphia and Baltimore two each, St. Louis, Milwaukee, Lawrence, and Holyoke one each. From *whooping-cough*, New York five, Philadelphia and Baltimore two each, Chelsea one. From *puerperal fever*, St. Louis three, New York two, Philadelphia and Milwaukee one each. From *small-pox*, Philadelphia, St. Louis, and Nashville, one each.

Five cases of small-pox were reported in St. Louis; scarlet fever 35, diphtheria 21, and typhoid fever six in Boston; scarlet fever nine and diphtheria seven in Milwaukee.

In 95 cities and towns of Massachusetts, with an estimated population of 1,377,016 (estimated population of the State 1,955,104), the total death-rate for the week was 16.28 against 19.26 and 16.59 for the previous two weeks.

For the week ending January 19th, in 167 German cities and towns, with an estimated population of 8,621,321, the death-rate was 24.8. Deaths reported 4107; under five years of age, 1952; consumption 572, lung diseases 528, diphtheria and croup 273, diarrhœal diseases 125, measles and rötheln 82, scarlet fever 69, whooping-cough 65, typhoid fever 47, puerperal fever 27, small-pox (Zittau one) one. The death-rates ranged from 13.2 in Metz to 39.2 in Essen; Königsberg 33.5; Breslau 32; Munich 28.2; Dresden 26.8; Berlin 22.7; Leipzig 35.4; Hamburg 24.7; Cologne 25.2; Frankfort a. M. 17.8; Strasburg 22.

For the week ending January 19th, in the Swiss towns, there were 25 deaths from consumption, lung diseases 25, diarrhœal diseases 13, diphtheria and croup seven, whooping-cough seven, measles four, typhoid fever three, scarlet fever two, small-pox two, puerperal fever one. The death-rates were, at Geneva 19.4; Zurich 15.8; Basle 13.2; Berne 26.7.

The meteorological record for the week ending February 16th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM FEBRUARY 16, 1884, TO FEBRUARY 21, 1884.

PERIN, GLOVER, lieutenant-colonel and surgeon, medical director, is granted one month's leave of absence, with permission to apply at Division Headquarters, Missouri, for an extension of one month. S. O. 16, Department of Dakota, February 9, 1884.

WILSON, GEORGE F., first lieutenant and assistant surgeon. Assigned to duty at Fort Walla Walla, W. T. S. O. 14, Department of the Columbia, February 5, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING FEBRUARY 23, 1884.

NASH, F. S., passed assistant surgeon, detached from the U. S. S. Dispatch, and waiting orders.

RUSH, W. H., passed assistant surgeon, detached from the Minnesota, and ordered to duty on board the Dispatch.

HALL, J. H., passed assistant surgeon, to the Minnesota.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AT BELFAST. MEETING OF THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

WE have received from Sir William MacCormac the following announcement in regard to the meetings of the British Medical Association at Belfast, and of the International Medical Congress at Copenhagen, next July and August, from which those desirous of attending will see how they can best combine both occasions.

The fifty-second annual meeting of the British Medical Association will be held on July 29, 30, and 31, and August 1, 1884, at Belfast, under the presidency of James Cuming, M. A., M. D., Professor of Medicine, Queen's College, Belfast. The Address in Medicine will be delivered by Sir Andrew Clark, Bart., M. D., F. R. C. P., Physician and Lecturer on Clinical Medicine, London Hospital. The Address in Obstetric Medicine will be delivered by George H. Kidd, M. D., F. R. C. S. I., Master of the Coombe Lying-in Hospital, Dublin. The Address in Physiology will be delivered by Peter Redfern, M. D., F. R. C. S. E., Professor of Anatomy and Physiology, Queen's College, Belfast.

Visitors coming from America to attend this meeting can travel by any of the following routes: —

(1.) A Cunard steamer will leave (*a*) New York on Wednesday, July 16th, arriving in Queenstown about the following Thursday week, July 24th. (*b.*) Boston on Saturday, July 19th, reaching Queenstown the following Monday week, July 28th.

(2.) A White Star steamer will leave New York on Saturday, July 12th, and on Saturday, July 19th; due at Queenstown about July 20th and July 27th.

(3.) An Inman steamer will leave New York on Tuesday, July 15th; due at Queenstown about July 23d.

(4.) An Allan steamer will leave Quebec on Saturday, July 19th, arriving in Londonderry about the 26th or 28th July.

(5.) An Anchor steamer will leave New York on Saturday, July 19th; due at Londonderry on July 29th.

Londonderry is ninety-five miles from Belfast, and trains run daily between the two places.

The route from Queenstown to Belfast is from Queenstown to Cork, Cork to Dublin (one hundred and sixty-five miles by train), and Dublin to Belfast (one hundred and thirteen miles).

MEETING OF THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

The time of the meeting of the British Medical Association at Belfast has been fixed so as not to interfere with the International Medical Congress, which is to begin at Copenhagen on 10th August.

A steamer will leave Hull (England) on August 2d and 9th for Copenhagen; and on August 5th a steamer will leave Leith (Scotland) for Copenhagen. Both these places (Hull and Leith) can be reached on any day by leaving Belfast on the previous evening by the cross-channel steamers. Visitors after attending the meeting of the British Medical Association in Belfast will have ample time to travel to Copenhagen for the Congress.

Communications in reference to the meeting of the British Medical Association at Belfast to be addressed to the Honorable Local Secretaries, John Moore, M. D., Alex. Dempsey, M. D., John W. Byers, M. A., M. D.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION. — There will be a meeting of the Section at 19 Boylston Place on Wednesday evening, March 5th, at 7.45 o'clock. Communication: Excision of a Portion of Intestine, including part of the Ileo-Cœcal Valve, for the Cure of Fæcal Fistula in the Right Groin, Dr. C. B. Porter. S. J. MIXTER, *Secretary.*

DEATH. — Died, at Williamstown, Mass., February 24, 1884, Henry Lyman Sabin, M. D., M. M. S. S., aged eighty-three years.

APPOINTMENT. — Dr. E. N. Whittier has been appointed Visiting Physician at the Massachusetts General Hospital.

BOOKS AND PAMPHLETS RECEIVED. — A Manual of Medical Jurisprudence, with Special Reference to Diseases and Injuries of the Nervous System. By Allan McLane Hamilton, M. D. With Illustrattons. New York: Bermingham & Co. 1883.

The Hip and its Diseases. By V. P. Gibney, A. M., M. D., Professor of Orthopædic Surgery in the New York Polyclinic, etc. New York: Bermingham & Co. 1884.

A Manual of Obstetrics. By A. F. A. King, M. D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, etc. With Fifty-Nine Illustrations. Second Edition. Philadelphia: Henry C. Lea's Son & Co. 1884.

Original Articles.

GENERAL PARALYSIS OF THE INSANE.

BY GEORGE F. JELLY, M. D.

I CANNOT hope to add anything to the already existing knowledge of this disease, but its rapid increase in modern times, its insidious beginning in many instances, the importance of its early detection, and its fatal character, make it one of the most interesting of brain diseases, and I shall narrate briefly a few cases which have come under my personal observation at the McLean Asylum and in private practice.

The French physicians first described general paralysis as a distinct disease. Esquirol recognized insanity with paralysis as incurable, but looked upon the latter symptom simply as a complication and not as a part of the disease.

In 1822 M. Bayle for the first time noted that the mental disturbance and paralysis were synchronous. M. Delaye in 1824 thought it not always accompanied by insanity, and that it was a softening or atrophy of the brain.

In 1826 M. Calmeil gave a most complete account of the disease, and has therefore generally been regarded as its discoverer.

General paralysis may be defined as a disease of the brain marked by general and progressive loss of coördinating power over the muscles, especially those of speech and locomotion, with greater or less impairment of sensation, always tending to dementia, and characterized by a sense of well being or actual delusions of an exalted character.

It is essentially a disease of civilization and of modern times, is much more common in the cities than in the country, and attacks by preference the robust and vigorous rather than the sick or those whose constitutions are weak congenitally or from the effects of disease.

More than any other serious mental disease it appears in persons in whom insanity is not an inheritance, chiefly in men who are in the prime of life, from thirty-five to fifty years of age. It is rare in persons under thirty or over sixty. I have seen one case in a man of twenty-six, and within a fortnight have examined a man sixty-four years old who presented all the characteristic symptoms of the disease. Most of the cases coming under my own observation have been in persons between forty and fifty. In women the disease is comparatively rare, but I am unable to give definite statistics in regard to the relative proportion between men and women. It is about one in ten or twelve.

There are at the present time at the Taunton Hospital ten male and three female paretics; at the Worcester Hospital there are twelve male and one female paretics; and at the Danvers Hospital there are forty-one male and fourteen female paretics, — making a total of eighteen females in a total of eighty-one cases, which I should think a larger proportion than usual. The whole number of patients in the three hospitals is two thousand and fifty-six — nine hundred and eighty-four men, and one thousand and seventy-two women.

The most common causes of general paralysis are excessive drinking, excessive sexual indulgence, overwork, and excessive or prolonged mental anxiety. Not infrequently some shock or acutely painful impression upon the moral sensibilities seems to furnish the additional weight needed to overcome a brain already tottering. So important a part does this strain or shock often play as a cause of this disease that the late Dr. Tyler was accustomed to say that the case was rare in which it was not a factor. General paralysis is described as having three periods: —

(1.) Commencement period or period of incubation.
(2.) Maniacal period.
(3.) Period of chronic mania, lapsing into dementia, with utter prostration of mind and body.

These periods often run into each other, and the first may escape the notice of friends and even of physicians unless they are accustomed to observe patients affected with this disease, but sooner or later it presents both motor and mental symptoms, which are characteristic, and if the disease runs its course and no intercurrent disease supervenes no portion of the body escapes.

In the first period the patient may simply be noticed to have changed, to be more irritable, more easily excited, less able to attend to business, more forgetful, less careful of money, and less shrewd in bargains. There is, if I may so express it, a peculiar "damaged" condition of mind, which gives the friends anxiety, but of which the patient is entirely unconscious. It is during this early stage that the patient may commit irregularities in business and in his moral conduct, may wreck his own and others' fortunes, and may ruin the reputation and prospects of his entire life. Hence the necessity of the early recognition of the disease, that its victim may be restrained in some way and protected from himself. There soon develops some difficulty in articulating certain words, especially those abounding in consonants; there is a tremor of lips and tongue, like that of a person about to weep; and it is observed that he drags one or both feet in walking. He now becomes extravagant and passes into the period of excitement. He considers himself all-powerful, believes that he owns everything, and talks constantly of the most extensive projects — a trip to the moon, pumping the Atlantic Ocean dry, and invents wonderful machines. At this time he is often very licentious, and talks much of his sexual powers and his influence over women. He is indifferent to his friends, is untidy in dress, and does not observe the proprieties of life. He may become violent at the slightest provocation, especially if any attempt is made to control or oppose him, and then is very dangerous, his weakened mind being capable of great fury, resembling the excitement following an epileptic seizure.

While in the excited period he is often taken to an insane hospital. There he soon settles down and becomes contented and happy, and owns the whole establishment. He considers himself well, and his complacency and self satisfaction continue through the whole course of the disease. The delusions change rapidly; there is great incoherence; when questioned he contradicts himself, and when his delusions are proved false he may admit their falsity in one moment and reassert them the next. Hallucinations of sight and hearing are not infrequent.

Sometimes epileptic or apoplectic seizures occur among the earliest symptoms, especially those of an

[1] Read before the Boston Society for Medical Improvement, February 25, 1884.

epileptic nature, which may be the first warning of the serious nature of the malady. During the progress of the disease they are very common, and may cause death at any time, and if frequent the mental failure is very rapid.

In the later stages of the disease the paralysis increases, until he is no longer able to walk at all; the difficulty in articulation becomes worse, and produces a mere unintelligible jargon; the mind becomes incapable of any effort whatever; the sphincters are relaxed, and the patient dies from exhaustion; from choking owing to inability to swallow; suddenly, from convulsions or apoplexy; from serous effusion into the brain, or from some intercurrent disease, as pneumonia, diarrhœa, or septicæmia from bedsores.

The incipient stage may be one of melancholia instead of exaltation, which, however, is comparatively rare, and is distinguished from ordinary melancholia by the greater mental weakness; there is no method, and there are no connected and good arguments.

The writing of a general paralytic is characteristic, and is often one of the first symptoms to attract attention. At first only a certain tremulousness may be noticed; then words are left out and misspelled, and as the disease progresses the tremulousness and indistinctness are more and more marked until the writing is entirely illegible.

The peculiarities in walking arise from the loss of coördinating power and increasing paralysis. The gait is stiff, the patient moving with a jerking, uncertain movement, though he may walk fast. He easily trips, and sooner or later shuffles, and as he progresses a peculiar straddling gait is seen, and finally he drags his legs after him in an indefinite, peculiar manner, as if they did not belong to him. Sometimes the gait is high stepping, and the patient walks with erect head.

There is always more or less paralysis of sensation, which increases as the disease advances, and the sensibility finally disappears.

The condition of the patellar tendon reflex is of some diagnostic value. In certain cases it is exaggerated, in others normal, and in still others below normal. In the majority of cases where there is any change it is supra-normal in the early stages of the disease.

Well-marked exaggeration in both legs is strong corroborative evidence of general paralysis; diminution or absence of it is decidedly less so, but has some value.

Where patellar reflex is absent disordered gait is among the first symptoms. There is generally inequality of the pupils, in some cases there is dilatation of both pupils, and sometimes the pupils are both abnormally small, mere pin holes, as in a case which I have had under observation for several months.

There is often no great change in the temperature of general paralytics. It averages a little above normal, but there is nothing diagnostic in it. There is a noticeable difference between the morning and evening temperature, and the prognosis as to time may be based to a certain extent upon the amount of this variation rather than upon any great or continuous elevation.

An ophthalmoscopic examination of the eyes of general paralytics often reveals atrophy of the optic disks, but as this change is frequent in other forms of cerebral disease its existence is corroborative rather than diagnostic.

The diagnosis in well-marked cases of general paralysis is easy, no other disease presenting the same combination of symptoms, excitement, extravagance, loss of memory, tremor of lips and tongue, and impairment of gait.

Sometimes in the somewhat rare cases where maniacal excitement is the earliest symptom, and there is no defect in the speech and no trouble in walking, even if delusions are extravagant, it may be difficult to make a positive diagnosis between general paralysis and acute mania. We must then await developments before giving a positive opinion. There are, however, certain impressions of general mental weakness which such cases give which will help very much in forming a decided opinion. Later in the disease there may again be difficulty, unless the physician is furnished with a full history of the case from its commencement. Advanced dementia, with hesitation in speech, may give rise to some doubt, but the absence of the peculiar muscular tremors in lips and tongue, and the optimistic view of things taken by general paralytics, even when very feeble, will help settle the diagnosis.

In the epileptic seizures of general paralysis the tongue is seldom bitten, the insensibility following a fit is much more deep, and the impairing effect of each seizure is much more apparent than in true epilepsy. In the grand mal of epilepsy the outcry which precedes the convulsion is characteristic, but is not heard in general paralysis.

Sometimes locomotor ataxia has been mistaken for general paralysis, but the general history of the case and the absence of mental symptoms would eliminate the latter disease.

The prognosis in this disease is always unfavorable. Remissions of active symptoms, which may continue for some months even, are not very unusual, but a relapse and eventual death must be expected. A few cases of recovery have been reported, but they lack the confirming test of time. The average duration of general paralysis is from two to three years, though a few cases have lived five, and, it is said, even ten and twelve years. I have in mind two undoubted cases, perfectly characteristic in every respect, one of which is of eight years' and the other of six years' duration. Much will depend in each case upon the violence or acuteness of the symptoms, the previous history of the individual, and the care which he receives.

In one of our public institutions, whose superintendent is a very careful and accurate observer, a patient with general paralysis was considered a case of locomotor ataxia for a year, till the development of disease made the diagnosis plain. A comparison of the symptoms of the two diseases shows the following differences: —

GENERAL PARALYSIS.	LOCOMOTOR ATAXIA.
Mental symptoms generally though not always first. Motor symptoms secondary.	Motor symptoms primary, following acute pain in distal part.
Extravagant delusions and violence.	Mental symptoms secondary, and are failing memory, with gradual impairment, without excitement.
Great sexual excitement.	No sexual desire and loss of sexual power.
Progress rapid.	May extend over ten or twelve years.
From above down.	From below up.

Very little can be said in regard to treatment. It must be mainly palliative, and directed to rendering less rapid the ravages of the disease. Quiet, a carefully regulated life, and the removal from everything which has a tendency to excite are essentials, and when there is much excitement these can rarely be attained outside of an insane hospital. Various emergencies and conditions call for medical treatment, and sedatives, tonics, and in the later stages stimulants may be useful, but nothing curative can be hoped for from any treatment.

The pathology of general paralysis is still debatable ground, but is admitted to be a degenerative inflammation of the cortical portion of the brain. Its inflammatory character is denoted by the post-mortem appearances. Those most commonly seen are adhesions of the dura mater, the vessels of which are often distended, and on its inner surface are found layers of hæmorrhagic exudation. The arachnoid is milky and thickened, studded with Pacchionian granules, and united to the dura mater. It is sometimes separated from the pia mater by effusion, and sometimes firmly adherent to it.

The pia mater and the cerebral cortex present the most pathognomonic signs of the disease. It adheres to the convolutions so intimately that portions of the latter come away with it, leaving a reddened surface. These appearances are seen chiefly in the frontal, posterior central, and parietal regions. The points of adhesion may be few or numerous, but are confined to the summits of the gyri. When the pia mater is removed the cortical substance is found atrophied in cases of average duration. Not only is there atrophy of the cortex, but also small capillary apoplexies may be seen. If the patient dies early in the disease we do not find the adhesions of the later stages, but only hyperæmia, with some opacity of the arachnoid. The vessels of the brain are often tortuous and varicose, and their walls are thickened; this is especially true of the veins of the pia mater. There may be effusions of serum or blood into the ventricles and sinuses, which fill the place of the atrophied brain.

There may be the same changes in the spinal cord and its membranes, but Westphal does not connect these appearances with the diseased conditions found in the brain (which is the true seat of the disease), and thinks them independent of each other. General paralysis is essentially a cerebral disease.

Dr. Blandford, in his work on Insanity and its Treatment, says: "That the cortex is the seat of this disease can hardly be doubted if we reflect that after all it is an insanity resembling in many respects the ordinary non-fatal insanity which we term mania. The 'pars affecta' is one and the same. The line of demarkation between ordinary insanity and general paralysis is exceedingly fine, and the whole history of the latter points to a difference in degree rather than in kind. That general paralysis is intractable and progressive is the fact that we are certain of. The hyperæmia which accompanies curable mania subsides and the disease vanishes. The hyperæmia of general paralysis becomes a slowly advancing inflammation which destroys the tissue."

CASE I. I. G., aged forty-three, single, merchant. Admitted to the McLean Asylum July 22, 1869. No insanity in family. He has been a man of very convivial habits. One year before admission he found himself unable to do his work, and retired from business. Of late he has been very extravagant, restless, and excited. His excitement passing beyond the control of his friends, he was sent to the asylum. On admission his speech was thick and his lips tremulous; he was self-satisfied and extravagant. Memory poor.

August 31st. He is the most contented and happy patient in the house. Is becoming stout. Thinks himself a very expert player of whist and euchre, but cannot follow the game. Becomes gradually duller and thicker.

In January, 1870, speech more impaired.

March 8th, eight months after admission, was semiconscious for an hour and a half, and the next day there was a repetition of the same condition. After these seizures the thickness of speech and dullness of intellect increased. Strange and deluded. Believed that the Lord was in his room. His mother died about this time, but when told of it he was affected only momentarily.

April 2d. Very restless, full of wants and schemes. Says that his mother is alive, and wishes to go to her. Is noisy at night and destructive. Losing flesh.

One month afterwards he had an apoplectic seizure, and could not swallow for twenty-four hours. After this he rallied, but was very weak and incoherent.

June 7th. Could walk with difficulty, and could take only liquid nourishment, but was in the best of spirits; considered his room magnificent, and believed himself quite well and possessed of great physical strength.

A month later he became highly excited, noisy, very filthy, and utterly incoherent. This excitement told upon his strength, and after being confined to his bed a week with symptoms of effusion he died, after one year's residence in the asylum, and two years from the commencement of the disease.

CASE II. F. A. B., aged thirty, married, innkeeper. Admitted August 31, 1869. For three months had been queer and excited. Much worried by the enforcement of prohibitory liquor law. On admission very much excited; believed himself Napoleon I. Speech thick, lips tremulous, gait enfeebled and shuffling.

His condition January 21, 1870, five months after admission, was much the same, except that he had advanced in dementia and feebleness. His delusions continued, and after nine months' residence in the asylum he was transferred to the Boston Lunatic Hospital, where he died within two years from the commencement of the disease.

CASE III. W. B., aged forty-five, widower, lawyer, native of New Hampshire. Admitted May 12, 1870. His father was subject to periods of depression. Patient was married ten years since, but his wife lived only six weeks. Her early death gave rise to talk on the part of his acquaintances, and he was blamed though there seems to have been no reason to believe him in fault. He had a lawsuit with his father-in-law about his wife's property, was defeated, became sullen and morose, and has since lived much by himself, and has dwelt upon his treatment by others. Has considerable property in real estate, and has had a very annoying class of tenants. Two years ago became very licentious, and he has been much addicted to masturbation.

For months his friends have noticed a change, and think that he has not appeared natural. Three weeks before admission he seemed very dull and stupid, was

much troubled with nausea, and it was noticed that there was difficulty in articulation, and that he dragged his feet. He soon rallied from this condition, talked much and at random on business matters, and wrote many letters full of wild projects. When he came to the asylum talked extravagantly of his plans and schemes, and his speech and walk were affected. Had much to say of buying elephants to do his farm work, said that an acre or two adjoining would be worth $25,000, styled himself the Astor of New Hampshire. Remained at the asylum willingly, and was at once at home. Said all the implements on his farm, including troughs for the pigs, were of solid silver. There was no great change for a month except that he increased in extravagance, and manifested more excitement, and was very obscene. He masturbated on all possible occasions. During next two months there was great excitement accompanied by threats, great irritability, and violence. During the next two months he was more quiet, and less extravagant, decidedly more sane, and generally quite gentlemanly in his conduct, but tremor of lips and mental enfeeblement were always apparent. He then became more unsettled and excitable, and had several dull, partially insensible attacks without convulsions, during which he vomited, and after which he was always weaker, more confused, and more excited. Often his attempts to talk were mere jargon, and his gait very feeble. These alternations continued steadily, he lost ground mentally and physically, and his incoherence and exalted ideas increased. Fifteen months after admission had his first epileptiform attack when exercising out-of-doors. From the early attacks he rallied, but they soon became very frequent, and he failed much more rapidly. His extravagance continued, and so long as he could talk he spoke constantly of his great sexual power, his powerful influence with the female sex, and insisted that Queen Victoria, whose daughter he had married, had built him a golden palace in the centre of his farm.

He died in epileptic convulsions three years and six months after admission to the asylum, and not far from five years from the first appearance of the disease. No autopsy.

(*To be continued.*)

CLINICAL ASPECTS OF CEREBRAL SYPHILIS.[1]

BY HORATIO C. WOOD, M. D.,

Professor of Diseases of the Nervous System in the University of Pennsylvania.

Paralysis. — When it is remembered that a syphilitic exudation may appear at almost any position in the brain, that spots of encephalic softening are a not rare result of the infection, that syphilitic disease is a common cause of cerebral hæmorrhage — it is plain that a specific palsy may be of any conceivable variety, and affect either the sensory, motor, or intellectual sphere. The mode of onset is as various as the character of the palsy. The attack may be instantaneous, sudden, or gradual. The gradual development of the syphilitic gumma would lead us, *à priori*, to expect an equally gradual development of the palsy; but experience shows that in a large proportion of the cases the palsy develops suddenly, with or without the occurrence of an apoplectic or epileptic fit. Under these circumstances it will be usually noted that the resulting palsy is incomplete; in rare instances it may be at its worst when the patient awakes from the apoplectic seizure, but mostly it progressively increases for a few hours, and then becomes stationary. These sudden partial palsies probably result from an intense congestion around the seat of disease, or from stoppage of the circulation in the same locality; but whatever their mechanism may be, it is important to distinguish them from palsies which are due to hæmorrhage. I believe this can usually be done by noting the degree of paralysis.

A suddenly developed, *complete* hemiplegia, or other paralysis, may be considered as in all probability either hæmorrhagic or produced by a thrombus so large that the results will be disorganization of the brain substance, and a future no more hopeful than that of a clot. On the other hand, an *incomplete* palsy may be rationally believed to be due to pressure or other removable cause, and this belief is much strengthened by a gradual development. The bearing of these facts upon prognosis it is scarcely necessary to point out.

Although the gummæ may develop at almost any point, they especially affect the base of the brain, and are prone to involve the nerves which issue from it. Morbid exudations, not tubercular nor syphilitic, are very rare in this region. Hence a rapidly but not abruptly appearing strabismus, ptosis, dilated pupil, or any paralytic eye symptom in the adult, is usually of syphilitic nature. Syphilitic facial palsy is not so frequent, whilst paralysis of the nerve from rheumatic and other inflammation within its bony canal are very common. Paralysis of the facial may therefore be specific, but it is of no diagnostic value. Since syphilitic palsies about the head are in most instances due to pressure upon the nerve trunks, the electrical reactions of degeneration are present in the affected muscles.

There is one peculiarity about specific palsies which has already been alluded to as frequently present, namely, a temporary, transient, fugitive, varying character and seat. Thus an arm may be weak to-day, strong to-morrow, and the next day feeble again, or the recovered arm may retain its power, and a leg fail in its stead. These transient palsies are much more apt to involve large than small brain territories. The explanation of their largeness, fugitiveness, and incompleteness is that they are not directly due to clots or other structural changes, but to congestions of the brain tissues in the neighborhood of gummatous exudations. It is easily seen why a squint will remain when the accompanying monoplegia disappears.

Motor palsies are more frequent than sensory affections in syphilis, but hemianæsthesia, localized anæsthetic tracts, indeed any form of sensory paralysis, may occur. Numbness, formications, all varieties of paræsthesia are frequently felt in the face, body, or extremities. Violent peripheral neuralgic pains are rare, and generally when present denote neuritis. Professor Huguenin, however, reports [2] a case in which a severe trigeminal anæsthesia dolorosa had existed during life, as the only cerebral symptom, and death occurring from lung disease, a small gumma was found on the sella turcica pressing upon the Gasserian ganglion.

The special senses are liable to suffer from the invasion of their territories by cerebral syphilis, and the

[1] Continued from page 200.

[2] Schwiez. Corr. Blat., 1875.

resulting palsies follow courses and have clinical histories parallel to those of the motor sphere. The onset may be sudden, or gradual, the result temporary or permanent. Dr. Charles Mauriac[1] reports a case in which the patient was frequently seized with sudden attacks of severe frontal pain and complete blindness, lasting from a quarter to half an hour; at other times the same patient had spells of aphasia lasting only for one or two minutes. In a case still under my care with unmistakable signs of cerebral syphilis the man was suddenly and unaccountably seized with complete deafness which after some days disappeared in the course of a few hours. Like other syphilitic palsies, therefore, paralyses of special senses may come on suddenly or gradually, and may occur paroxysmally.

Among the palsies of cerebral syphilis must be ranked aphasia. An examination of recorded cases shows that it is subject to vagaries and laws similar to those connected with other specific cerebral palsies. It is usually a symptom of advanced disease, but may certainly develop as one of the first evidences of cerebral syphilis.

Coming on after an apoplectic or epileptic fit, it may be complete or incomplete: owing to the smallness of the centre involved, and the ease with which its function is held in abeyance, a total loss of word thought is not so decisive as to the existence of cerebral hæmorrhage as is a total motor palsy. Like hemiplegia or monoplegia, specific aphasia is sometimes transitory and paroxysmal. Dr. Buzzard[2] records several such cases. Dr. Charles Mauriac[3] details a very curious case in which a patient, after long suffering from headache, was seized by sudden loss of power in the right hand and fingers, lasting about ten minutes only, but recurring many times a day. After this had continued some time the paroxysms became more completely paralytic and were accompanied by loss of power of finding words, the height of the crises in the palsy and aphasia being simultaneously reached. For a whole month these attacks occurred five or six times a day, without other symptoms except headache, and then the patient became persistently paralytic and aphasic, but finally recovered.

To describe the different forms of specific aphasia and their mechanism of production would be to enter upon a discussion of aphasia itself, a discussion out of place here. Suffice to say that every conceivable form of the disorder may be induced by syphilis.

Owing to the centres of speech being situated in the cortical portion of the brain, aphasia in cerebral syphilis is very frequently associated with epilepsy. Of course right-sided palsy and aphasia are united in syphilitic as in other disorders. If, however, the statistics given by M. Tanowsky[4] be reliable, syphilitic aphasia is associated with left-sided hemiplegia in a most extraordinarily large proportion. Thus in fifty-three cases collected by Mr. Tanowsky, eighteen times was there right-sided hemiplegia, and fourteen times left-sided hemiplegia, the other cases being not at all hemiplegic. Judging from the autopsy on a case reported in Mauriac's brochure this concurrence of left-sided paralysis and aphasia depends partly upon the great frequency of multiple brain lesions in syphilis, and partly upon the habitual involvement of large territories of the gray matter secondarily to diseased membrane. An important practical deduction is that the conjoint existence of left hemiplegia and aphasia is almost diagnostic of cerebral syphilis.

Probably amongst the palsies may be considered the disturbances of the renal functions, which are rarely met with in cerebral syphilis, and which are probably usually dependent upon the specific exudation pressing upon the vaso-motor centres in the medulla. Fournier speaks of having notes of six cases in which polyuria with its accompaniment, polydipsia, was present, and details a case in which the specific growth was found in the floor of the fourth ventricle. Cases have been reported in which true saccharine diabetes has been present,[5] and I can add to these an observation of my own. The symptoms, which occurred in a man of middle age with a distinct specific history, were headache, nearly complete hemiplegia, and mental failure, associated with the passage of comparatively small quantities of a urine so highly saccharine as to be really a syrup. Under the influence of the iodide of potassium the sugar in a few weeks disappeared from the urine.

Epilepsy. — Epileptic attacks are a very common symptom of meningeal syphilis, and are of great diagnostic value. The occurrence in an adult of an epileptic attack, or of an apoplectic fit, or of a hemiplegia after a history of intense and protracted headache, should always excite grave suspicion.

Before I read Professor Fournier's work on Nervous Syphilis, I taught that an epilepsy appearing after thirty years of age was very rarely, if ever, essential epilepsy, and unless alcoholism, uræmic poison, or other adequate cause could be found was in nine cases out of ten specific; and I therefore quote with satisfaction Professor Fournier's words: "L'épilepsie vraie, ne fait jamais son premier début à l'âge adulte, à l'âge mûr. Si un homme adulte, au dessus de 30, 35 à 40 ans, vient à être pris pour la première fois d'une crise épileptique, et cela dans la cours d'une bonne santé apparente, il y a, je vous le répète, huit ou neuf chances sur dix pour que cette épilepsie soit d'origine syphilitique."

Syphilitic epilepsy may occur either in the form of petit mal or of the haut mal, and in either case may take on the exact characters and sequence of phenomena which belong to the so-called idiopathic or essential epilepsy. The momentary loss of consciousness of petit mal will usually, however, be found to be associated with attacks in which, although voluntary power is suspended, memory recalls what has happened during the paroxysm; attacks, therefore, which simulate those of hysteria, and may lead to an error of diagnosis.

Even in the fully-developed type of the convulsions the aura is only rarely present. Its absence is not, however, of diagnostic value, because it is frequently not present in true essential epilepsy, and it may be pronounced in specific disease. It is said, that when in an individual case the aura has once appeared, the same type or form of approach of the convulsion is thereafter rigidly adhered to. The aura is sometimes bizarre; a severe pain in the foot, a localized cramp, a peculiar sensation, indescribable and unreal in its feeling, may be the first warning of the attack.

In many, perhaps most cases of specific convulsions, instead of a paroxysm of essential epilepsy being closely simulated, the movements are in the onset, or, more

[1] Aphasie et Hemiplégie droite Syphilit., Paris, 1877.

rarely, throughout the paroxysm, unilateral; indeed, they may be confined to one extremity. This restriction of movement has been held to be almost characteristic of syphilitic epilepsy, but it is not so. Whatever diagnostic significance such restriction of the convulsion has is simply to indicate that the fit is due to a cortical organic lesion of some kind. Tumors, scleroses, and other organic lesions of the brain cortex are as prone to cause unilateral or monoplegic epilepsy when they are not specific as when they are due to syphilis.

Sometimes an epilepsy, dependent upon a specific lesion implicating the brain cortex, may be replaced by a spasm which is more or less local and is not attended with any loss of consciousness. Thus, in a case now convalescent in the University Hospital, a man, aged about thirty-five, offered a history of repeated epileptic convulsions, but at the time of his entrance into the hospital, instead of epileptic attacks, there was a painless tic. The spasms, which were clonic, and occurred very many times a day — sometimes every five minutes — were very violent and mostly confined to the left facial nerve distribution. The trigeminus was never affected, but in the severer paroxysms the left hypoglossal and spinal accessory nerves were profoundly implicated in all of their branches. Once, fatal asphyxia from recurrent laryngeal spasm of the glottis was apparently averted only by the free inhalation of the nitrite of amyl. The sole other symptom was headache, but the specific history was clear, and the effect of antisyphilitic remedies rapid and pronounced.

Psychical Symptoms. — As already stated, apathy, somnolence, loss of memory, and general mental failure are the most frequent and characteristic mental symptoms of meningeal syphilis, but, as will be shown in the next chapter, syphilis is able to produce almost any form of insanity, and therefore mania, melancholia, erotic mania, delirium of grandeur, etc., etc., may develop along with the ordinary manifestation of cerebral syphilis, or may come on during an attack which has hitherto produced only the usual symptoms. Without attempting any exhaustive citation of cases, the following may be alluded to: —

Dr. A. Erlenmeyer reports[1] a case in which an attack of violent headache and vomiting was followed by paralysis of the right arm and paresis of the left leg with some mental depression; a little later the patient suddenly became very cheerful, and shortly afterwards manifested very distinctly delirium of grandeur with failure of memory. Dr. Batty Tuke reports[2] a case in which with aphasia, muscular wasting, strabismus, and various palsies there were delusions and hallucinations.

In the same journal, April, 1869, Dr. S. D. Williams reports a case in which there were paroxysmal violent attacks of frontal headache. The woman was very dirty in her habits, only ate when fed, and existed in a state of hypochondriacal melancholy.

M. Leiderdorf details a case with headache, partial hemiplegia, great psychical disturbance, irritability, change of character, marked delirium of grandeur, epileptic attacks, and finally dementia, eventually cured with iodide of potassium.[3] Several cases illustrating different forms of insanity are reported by Dr. N. Manssurow.[4]

[1] Die luëtischen Psychosen.
[2] Journ. Ment. Sci., January, 1874, page 560.
[3] Medizin. Jahrbücher, xx., 1864, p. 114.
[4] Die Tertiäre Syphilis, Wein., 1877.

That the attacks of syphilitic insanity, like the palsies of syphilis, may at times be temporary and fugitive, is shown by a curious case reported by Dr. H. Hayes Newington,[5] in which along with headache, failure of memory, and ptosis in a syphilitic person there was a brief paroxysm of noisy insanity.

DISEASES OF BRAIN SUBSTANCE.

The psychical symptoms which are produced by syphilis are often very pronounced in cases in which the paralysis, headache, epilepsy, and other palpable manifestations show the presence of gross brain lesions. In the study of syphilitic disease of the brain membranes sufficient has been said in regard to these psychical disturbances, but the problem which now offers itself for solution is as to the existence or non-existence of syphilitic insanity, that is, of an insanity produced by specific contagion without the obvious presence of gummatous disease of the brain membranes. Very few alienists recognize the existence of a distinct affection entitled to be called syphilitic insanity, and there are some who deny that insanity is ever directly caused by syphilis. It is certain that insanity often occurs in the syphilitic, but syphilis is abundantly joined with alcoholism, poverty, mental distress, physical ruin, and various depressing emotions and conditions which are well known to be active exciting causes of mental disorder. It may well be that syphilis is in such way an indirect cause of an insanity, which under the circumstances could not be properly styled syphilitic.

If there be disease of the brain cortex produced directly by syphilis, of course such disease must give rise to mental disorders, and, if the lesion be situated in such a way as to affect the psychic and avoid the motor regions of the brain, it will produce mental disorder without paralysis, that is, a true insanity; again, if such brain disease be wide spread, involving the whole cortex, it will cause a progressive mental disorder, accompanied by gradual loss of power in all parts of the body and ending in dementia with general paralysis; or, in other words, it will produce an affection more or less closely resembling the so-called general paralysis of the insane, or dementia paralytica.

As a man having syphilis may have a disease which is not directly due to the syphilis, when a syphilitic person has any disorder there is only one positive way of determining how far said disorder is specific, namely, by studying its amenability to antisyphilitic treatment. In approaching the question whether a lesion found after death is specific or not, of course such a therapeutic test as that just given is inapplicable. We can only study as to the coexistence of the lesion in consideration with other lesions known to be specific. Such coexistence of course does not absolutely prove the specific nature of a nutritive change, but renders such nature exceedingly probable.

What has just been said foreshadows the method in which the subject in hand is to be here examined, and the present chapter naturally divides itself into two sections: the first considering the coexistence of anatomical alterations occurring in the cerebral substance with syphilitic affections of the brain membranes or blood-vessels, the second being a clinical study of syphilitic insanity.

In looking over literature I have found the following cases in which a cerebral sclerotic affection coincided with a gummatous disease of the membrane. Gross

[5] Journ. Ment. Sci., London, xix., 555.

and Lancereaux [1] report a case having a clear syphilitic history, in which the dura mater was adherent to the skull. The pia mater was not adherent. Beneath, upon the vault of the brain, was a gelatinous exudation. The upper cerebral substance was indurated, and pronounced by M. Robin after microscopic examination to be sclerosed. At the base of the brain were very atheromatous arteries and spots of marked softening.

Dr. Jos. J. Brown [2] reports a case in which the symptoms were melancholia, excessive irritability, violent outbursts of temper, very positive delusions, disordered gait ending in dementia. At the autopsy, which was very exhaustive, extensive syphilitic disease of the vessels of the brain and spinal cord was found. The pia mater was not adherent to the brain. The convolutions, particularly of the frontal and parietal lobes, were atrophied with very wide sulci, filled with bloody serum. The neuroglia of these convolutions was much increased and "appeared to be more molecular than normal, the cells were degenerated and in many places had disappeared, their places being only occupied by some granules." These changes were most marked in the frontal convolutions.

H. Schule reports [3] a very carefully and meritoriously studied case. The symptoms during life exactly simulated those of dementia paralytica. The affection commenced with an entire change in the disposition of the patient; from being taciturn, quiet, and very parsimonious, he became very excited, restless, and desiring continuously to buy in the shops. Then failure of memory, marked sense of well-being, carelessness and indifference for the future, developed consentaneously with failure of the power of walking, trembling of the hands, inequality of the pupils, and hesitating speech. There was next a period of melancholy, which was, in time, followed by continuous failure of mental and motor powers, and very pronounced delirium of grandeur, ending in complete dementia. Death finally occurred from universal palsy with progressive increase of the motor symptoms. At the autopsy characteristic syphilitic lesions were found in the skull, dura mater, larynx, liver, intestines, and testicles. The brain presented the macroscopic and microscopic characters of sclerosis and atrophy; the neuroglia was much increased, full of numerous nuclei, the ganglion cells destroyed. The vessels were very much diseased, some reduced to cords; their walls were greatly thickened, and full of long, spindle-shaped cells, sometimes also containing fatty granules.

Dr. C. E. Stedman and Robert T. Edes report [4] a case in which the symptoms were failure of health, ptosis, trigeminal palsy with pain (anæsthesia dolorosa), finally mental failure with gradual loss of power of motion and sensation. At the autopsy the following conditions were noted: apex of the temporal lobe adherent to dura mater and softened; exuded lymph in neighborhood of optic chiasm; sclerosis of right Gasserian ganglion, as shown in a marked increase of the neuroglia; degeneration of the basal arteries of the brain.

These cases are sufficient to demonstrate that sclerosis of the brain substance not only may coexist with a brain lesion, which is certainly specific in its character, but may also present the appearance of having developed *pari passu* with that lesion, and from the same cause.

It has already been stated in this memoir that cerebral meningeal syphilis may coexist with various forms of insanity, and cases have been cited in proof thereof. It is, of course, very probable that in some of such cases there has been that double lesion of membrane and gray brain matter which has just been demonstrated by report of autopsies; further, if we find that there is a syphilitic insanity, which exists without evidences of meningeal syphilis, and is capable of being cured by antispecific treatment, such insanity must be considered as representing the disease of the gray matter of the brain. Medical literature is so gigantic that it is impossible to exhaust it, but the list of cases given in the Table (see p. 224) is amply sufficient to prove the point at issue, namely, that there is a syphilitic insanity which exists without obvious meningeal disease, and is capable of being cured by antisyphilitic treatment.

A study of the brief analyses of symptoms given in the Table shows that syphilitic disease of the brain may cause any form of mania, but that the symptoms, however various they may be at first, end almost always in dementia unless relieved.

Of all the forms of insanity general paralysis is most closely and frequently simulated by specific brain disease. The exact relation of the diathesis to true incurable general paralysis it is very difficult to determine. It seems well established that amongst persons suffering from this disorder the proportion of syphilitics is not only much larger than normal, but also much larger than in other forms of insanity. Thus Dr. E. Mendel [5] found that in 146 cases of general paralysis 109, or seventy-five per cent., had a distinct history of syphilis, whilst in 101 cases of various other forms of primary insanity only eighteen per cent. had specific antecedents.

Various opinions might be cited as to the nature of this relation between the two disorders, but for want of space the curious reader is referred to the work just quoted, and to the thesis of C. Chauvet [6] for an epitome of the most important recorded opinions.

Those who suffer from syphilis are exposed in much greater proportion than are other persons to the ill effects of intemperance, sexual excesses, poverty, mental agony, and other well-established causes of general paralysis. It may be that in this is sufficient explanation of the frequency of general paralysis in syphilitics, but I incline to the belief that syphilis has some direct effect in producing the disease. However this may be, I think we must recognize as established the opinion of Voisin [7] that there is a syphilitic periencephalitis which presents symptoms closely resembling those of general paralysis. Such cases are examples of the pseudo-paralysie générale of Fournier.[8]

The question as to the diagnosis of these cases from the true incurable paresis is, of course, very important, and has been considered at great length by Voisin,[9] Fournier,[10] and Mickle.[11]

The points which have been relied upon as diagnostic of syphilitic pseudo-general paralysis are: —

5	M. Leidesdorf. Medizin. Jahrbücher, xx., 1864, 1.	Complete mania, played with his excrement, and entirely irrational.	Complete cure by iodide of potassium.
6	Dr. Beauregard. Gaz. Hebdom. de Sci. Med. de Bordeaux, 1880, page 64.	Symptoms resembling those of general paralysis.	Cure by iodide of potassium.
7	M. Rendu. Ibid.	Loss of memory, headache, irregularity of pupils, ambitious delirium, periods of excitement, others of depression, embarrassment of speech, access of furious delirium, ending in stupor.	Mercurial treatment, cure.
8	Ibid.	Hypochondria, irregularity of pupils, headache, failure of memory, melancholy, stupor.	Mercurial treatment, cure.
9	Dr. Albrecht Erlenmeyer. Die luëtischen Psychosen, Neuwied, 1877.	Melancholia, with hypochondriasis, sleeplessness, fear of men, and belief they were all leagued against him.	Iodide of potassium, cure.
10	Ibid.	Religious melancholia, with two attempts at suicide, ending in mania.	Iodide of potassium, cure.
11	Ibid.	At times very violent, yelling, shrieking, destroying everything she could get hands on, at times erotomania; no distinct history of infection, but her habits known to be bad, and had bone ozæna and other physical syphilitic signs.	Iodide of potassium, cure.
12	Ibid.	Epileptic attack, followed by a long soporose condition, ending in mental confusion, he not knowing his nearest friends, etc.; almost dementia.	Cured by mercurial inunction.
13	Ibid.	Great fear of gend'armes, etc., mania, with hallucinations, loud crying, yelling, etc., then convulsion, followed by great difficulty of speech.	Cured by mercurial inunctions, with iodide internally; subsequently return of convulsions, followed by hemiplegia and death.
14	Ibid.	Great unnatural vivacity and loquacity, wanted to buy everything, bragged of enormous gains at play, etc.; some trouble of speech.	Iodide of potassium, cure. Attended to business, and seems as well as before. Relapsed. (See Symptoms.)
—	Ibid. Relapse of Case 14.	Fifteen months after discharge from asylum relapse; symptoms developing very rapidly, delirium of grandeur of the most aggravated type, with marked progressive dementia, failure of power of speech, and finally of locomotion.	Failure of various antispecific treatment.
15	Dr. A. Erlenmeyer. Die luëtischen, etc.	Failure of mental powers, inequality of pupils, trembling of lip when speaking, uncertainty of gait, almost entire loss of memory, once temporary ptosis and strabismus.	Iodide of potassium in ascending doses failed. Recovery under mercurial inunctions.
16	Ibid.	Failure of mental powers, pronounced delirium of grandeur, hallucinations of hearing, failure of memory, strabismus and ptosis coming on late.	Iodide of potassium, corrosive sublimate injections. Cure.
17	Ibid.	Failure of memory and mental powers, slight ideas of grandeur, disturbance of sensibility and motility, aphasia coming on late.	Cure with use of iodide and mercurial inunctions.
18	Ibid.	Melancholy, great excitability, ideas of grandeur, after a long time sudden ptosis and strabismus.	Iodide of potassium failed: mercurial course improved; joint use cured patient.
19	Ibid.	Various cerebral nerve palsies, great relief by use of mercurial inunctions, then development of great excitement, delirium of grandeur, failure of memory and mental powers, and finally death from apoplexy; no autopsy.	
20	Dr. J. B. Chapin. Amer. Journ. Insanity, vol. xv., p. 249.	Melancholia, with attempted suicide, epilepsy, headache, somnolent spells.	Iodide of potassium, cure.
21	Ibid.	Acute mania, noisy, very destructive; syphilitic disease of tibia.	Iodide of potassium, cure.
22	Dr. Snell.	Maniacal excitement.	Cured by specific treatment.
23	William Smith. Brit. Med. Journ., July, 1868, page 30.	Apathetic melancholy, indelicate, speaking only in monosyllables, and much of the time not at all, sullen and menacing.	Rapidly cured by conjoint use of iodide and mercurial. The symptoms first developed three months after chancre.

The occurrence of headache, worse at night, and present amongst the prodromes.

An early, persistent insomnia or somnolence; early epileptiform attacks.

The exaltation being less marked, less persistent, and, perhaps, less associated with general maniacal restlessness and excitement.

The articulation being paralytic rather than paretic.

The absence of tremulousness, especially of the upper lip (Fournier).

The effect of antispecific remedies.

When the conditions in any case correspond with the characters just paragraphed, or when any of the distinguishing characteristics of brain syphilis, as previously given in this memoir, are present, the probability is that the disorder is specific and remediable. But the absence of these marks of specific disease is not proof that the patient is not suffering from syphilis. Headache may be absent in cerebral syphilis, as also may insomnia and somnolence. Epileptiform attacks are not always present in the pseudo-paralysis, and may be present in the genuine affection. A review of the cases previously tabulated shows that in several of them the megalomania was most pronounced, and a case with very pronounced delirium of grandeur in which the autopsy revealed unquestionably specific brain lesions may be found in Chauvet's Thesis, page 31.

I have myself seen symptoms of general paralysis occurring in persons with a specific history in which of these so-called diagnostic differences the therapeutic test was the only one that revealed the true nature of the disorder. In these persons a primary immediate diagnosis was simply impossible.

Case XIV. of our table is exceedingly interesting because it seems to represent as successively occurring in one individual both pseudo and true general paralysis. The symptoms of general paralysis in a syphilitic

subject disappeared under the use of mercury to return some months afterwards with increased violence, and with a new obstinacy that resisted with complete success antisyphilitic treatment. Such a case is some evidence that syphilis has the power to produce true general paralysis.

In conclusion I may state that it must be considered as at present proven that syphilis may produce a *disorder whose symptoms and lesions do not differ from those of general paralysis; that true general paralysis is very frequent in the syphilitic; that the only perceptible difference is one of curability; that the curable sclerosis may change into or be followed by the incurable form of the disease.* Whether under these circumstances it is philosophic to consider the so-called pseudo-general paralysis and general paralysis as essentially distinct affections each physician can well judge for himself.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M. D.

ANTHROPOLOGY.

A NUMBER of leading German anthropologists and anatomists have agreed to a scheme [1] determining a number of starting-points for measurements of the skull, which, if universally accepted, will do much to establish uniformity. The only feature of the scheme we will mention is the determination of the horizontal level of the skull, which is evidently of much importance, and which has already been referred to in these reports. The horizontal plane is the one determined by two straight lines which, on either side, connect the lowest point of the border of the orbit with the point in the upper border of the bony auditory meatus directly above the middle of the opening. It will be found that by this rule the face is thrown a little higher than by the simpler one, which is tolerably accurate, of making the upper border of the zigoma horizontal.

Dr. Paul Ricardi [2] has published a work in Italian on growth and stature, founded chiefly on observations made on the inhabitants of Modena and of the neighborhood. He finds that at birth there is little difference between the height and the breadth through the extended arms. Up to seven or eight years the latter measurement is almost always the less, but subsequently it is the greater. In the adult man, the height being 1000, the spread is 1045, and in woman 1015. On referring to Roberts' Anthropometry we find that he gives precisely the same proportions. According to Ricardi the maximum excess of the height over the spread is ten centimetres, while the maximum excess of the spread over the height may be as much as nineteen centimetres.

THE TOPOGRAPHY OF THE FEMALE THORAX.[3]

Professor Henke has written a paper to explain why, in his text-book on topographical anatomy, he has said but little of the difference of the relations of the thoracic organs in man and woman. It is well known that the sternum is absolutely smaller in woman, and it has been stated that the proportion of the manubrium to the body is characteristic of the sex. Hyrtl wrote: "I find the difference between the male and female sternum so clearly expressed by the proportion of the manubrium to the body that it is hardly possible to err in determining the sex. The manubrium of the female sternum exceeds half the length of the body, while the body in the male sternum is at least twice as long as the manubrium." According to Luschka "the body is usually twice as long as the manubrium in woman, and two and one half times as long in man." The writer of this report published [4] a series of measurements according to which the manubrium of the male sternum is to the body as 49 (—) is to 100, and the female as 52 (+) is to 100, thus apparently proving Hyrtl's rule, but the statistics showed that nearly half the cases were exceptions, and that thus the rule was too uncertain to be of value in any given instance. Henke refers to a paper by Strauch (which we have not seen) giving very different results. According to him in man the manubrium is to the body as 37.7 is to 100, and in woman as 71 is to 100. Henke suggests a new method, that of dividing the sternum into two pieces at the third costal cartilage. He finds the two about equal in man, and the lower smaller in woman. If it be true, according to whatever scheme of measurement be adopted, that the lower part of the bone is relatively smaller in woman, it would appear that the relations of the heart must be different in the sexes. Henke finds that there is a characteristic arrangement of the cartilages of the lower true ribs which practically supplies the deficiency of the sternum. We give a translation of his interesting description: "On the other hand, in the female thorax the lower half of the breast bone, without the ensiform cartilage, reckoning from the insertion of the third costal cartilage, is, as has been said, shorter than the upper, and at the same time more slender. The breadth does not increase below as in a well-developed male sternum. The insertions of the lower true ribs are necessarily crowded more together than in the male. There is no space even between the fifth and sixth; on the contrary their cartilages are usually united by a joint further out, which in the male only happens between the sixth and seventh. At the same time the arches of the two sides are so pressed together towards the middle that no place is left between them for the ensiform cartilage, which is consequently driven behind them. Instead of diverging they run here for some distance directly downwards, either close together or at least so near that, with the ensiform cartilage, they form a median continuation of the front wall of the chest, below the breast bone, and then diverge lower down. Even then their divergence is not so strong as in man, but such as to make a very sharp angle. Moreover, these cartilages of the lower true ribs are, relatively, much larger than in man, both longer and thicker, especially that of the seventh, which is most concerned in forming the border of the thorax below the angle. Thus, although their sternal ends reach higher, the points where they join the ribs are lower and nearer the middle line. As a whole they form a strong and steep border of the narrower and higher angle of the abdominal wall. The apex of the angle in which they meet above lies rather lower than the end of the breast bone, and yet about where it would lie in man, that is, twice as far from the top of the sternum as from the insertion of the third rib."

[2] Further statistics will be found in a review of the book in the Revue d'Anthropologie, deuxième série, tome vii., 1884.

[3] Archiv für Anatomie und Entwickelungsgeschichte, 1883, Heft 4, 5, and 6.

[4] Journal of Anatomy and Physiology, vol. xv., 1881.

From this it is clear that if in the male the lower border of the right ventricle lies across the lower border of the sternum, in the female it must be uncovered by that bone, but Henke points out that if instead of the lower end of the bone we speak of the thoracic angle the relations are practically the same. Professor Henke is, further, of the opinion that female clothing is the cause of this squeezing together of the ribs, although he admits that anatomical subjects for the most part are not of the class addicted to tight lacing. His arguments on this point fail to convince us.

THE FOLD OF THE NATES.[1]

Mr. Symington refers to the general view that the lower border of the gluteus maximus marks the fold of the nates or, according to some, forms it, and points out that Luschka has given a different and more correct account of the matter. Luschka, indeed, shows that the fold of the nates cannot be determined by the edge of the gluteus, which, in fact, crosses it, but that it is beneath a pad of fat, and that bands of connective tissue, passing through the fat, bind the skin to the tuberosity of the ischium and to the fascia lata. We will quote from Mr. Symington's description of the relations of the parts, which is accurate and instructive: "The lower border of the gluteus maximus passes from the coccyx downwards and outwards to about the juncture of the upper with the middle third of the shaft of the femur. As it passes rather more downwards than outwards the border is more internal than inferior. Taking the lower border as straight we found it formed an angle of about 145 degrees with the mesial line of the trunk. The gluteal sulcus, on the other hand, passes outwards and slightly upwards. It is continuous internally with the groove between the inner side of the thigh and the perinæum, and extends outwards below the ischial tuberosity towards the lower part of the great trochanter. It usually reaches about half way across the back of the thigh, and gradually disappears as it passes outwards; occasionally there are one or more transverse folds below it. Close to the middle line the gluteal sulcus will be found, in an average adult, three or four inches below the muscle, but, owing to the lower border of the muscle inclining downwards and outwards, while the gluteal fold extends transversely outwards, the two meet a little external to the middle of the lower border of the muscle, and then the fold passes on to the posterior surface of the muscle. The outer end of the lower border of the muscle reaches two or three inches lower down than the outer end of the gluteal fold." Mr. Symington shows this very prettily by fixing the fold to the deeper parts by pins, and then making a window through the skin both above and below it. He claims, moreover, that the fact can be demonstrated in the living subject. His theory of the production of the fold is essentially Luschka's, but he submits in addition that one factor is the prominence of the tuberosity of the ischium, and another the necessity of a fold in the skin behind the thigh to allow it to be flexed on the abdomen.

THE RELATIONS OF THE FISSURES OF THE BRAIN TO THE SURFACE.[2]

Mr. Hare offers a new method of determining the position of the fissure of Rolando. He has experimented on eleven heads by stretching a string over the vertex attached to pegs driven into the glabella and external occipital protuberance, then removing one side of the calvaria, and marking on the cord the position of the upper end of the fissure. He found that the distance from the glabella to the fissure was 55.7 per cent. of that between the pegs, of course, following the curves. The variations were slight, in no case amounting to one third of an inch, which is the more remarkable and important as the heads were of various shapes and sizes. The angle which the fissure makes with the median line ranged from sixty degrees to seventy-three degrees, averaging sixty-seven degrees. The parieto-occipital fissure was found in ten instances, on an average, five eighths of an inch in front of the lambdoidal suture. Its upper end, according to Mr. Hare, should be sought on the living subject one and seven eighths inches behind the top of the fissure of Rolando. The beginning of the fissure of Sylvius was found very constantly one and one eighth inches behind the external angular process of the frontal bone.

The author studied also the symmetry of the two halves of the brain. The fissure of Rolando was very symmetrical, that of Sylvius was symmetrical at its origin, but not throughout its course. The parieto-occipital fissure was much less regular. [We wonder, by the way, whether any part of the irregularity of the last-named fissure is at all owing to the blunder concerning it — emphasized by a foot-note — which has appeared in the recent editions of Gray's Anatomy.]

MOVEMENTS OF THE SHOULDER.[3]

We would call attention to a paper by Mr. Cathcart, of Edinburgh, on the movements of the shoulder girdle involved in those of the arm on the trunk, not so much by reason of its intrinsic importance, although it is valuable, as because it is a step in the right direction in the study of the actions of muscles. The actions of muscles are often deduced from their anatomical positions, or from the effect of stimulation, or by the study of paralyses, and though in this way we may ascertain tolerably accurately the action of individual muscles, we do not learn how many concur to produce any given movement, nor do we appreciate the relative importance of each. Mr. Cathcart has studied the question on the living model, and, indeed, on many. He pays a handsome compliment to Dr. Keen, of Philadelphia, who it will be remembered read a paper on this subject at the International Congress in London.

Mr. Cathcart points out that according to the usual teaching the action of raising the arm straight outwards as high as possible is divided into two stages: the first till it becomes horizontal, the second afterwards, and that we teach that in the first the humerus moves in the socket till it can move no more, and that in the second stage the shoulder girdle is raised, the scapula rotating at the same time. We omit his remarks on the action of the various muscles, and go on to his account of what actually takes place, which we give in part in his own words: —

"*First Stage.* It will be seen that while the arm is at rest the vertebral border of the scapula projects from the trunk, and that the venter is not closely applied to the chest wall, but that as soon as an effort is made to raise the arm the scapula is drawn more firmly against the ribs by the muscles passing to it

[1] Journal of Anatomy and Physiology, vol. xviii., part 2, January, 1884.

[2] Journal of Anatomy and Physiology, January, 1884.

[3] Journal of Anatomy and Physiology, vol. xviii., January, 1884.

from the trunk. When the arm in leaving the side reaches an angle of about 30°, the inferior angle of the scapula begins to rotate forwards, while the clavicle (best seen at the acromial end) moves upwards and backwards. From the beginning, the contraction of the deltoid and trapezius muscles can be seen and felt, as also that of the infra-spinatus, while that of the serratus magnus is with difficulty appreciated.

"*Second Stage.* The continued rotation of the scapula is at once evident, and on close examination it will be seen, that while the humerus moves with it at first, towards the end of the movement the scapula ceases to rotate, and the last part is performed by the humerus alone moving over the glenoid cavity; this will be rendered apparent if the direction of the spine of the scapula be compared with that of the humerus in the horizontal position and in the vertical above. The acromial end of the clavicle will be seen to rise and pass backwards, also to have a slight rotation on its long axis. The continued contraction of the trapezius, infra-spinatus, and deltoid muscles is apparent, while the increased contraction of the deltoid at its anterior part, and of the lower portion of the serratus magnus, is in each case perfectly clear."

Mr. Cathcart points out that the rotation of the scapula in the early part of the movement may be to some extent passive, that is to say, that it is drawn in part by the muscles passing from it to the humerus. He thinks that the movements of the clavicle lessen the strain needed to keep the body erect by bringing the weight of the arm more into line with the axis of the trunk. He says nothing of the action of the coracobrachialis, which Krause reckons as one of the muscles engaged in the movement when it is carried far, and it certainly seems plausible that it should act towards the end of the second stage.

THE VEINS OF THE PERINÆUM.[1]

Professor Tschaussow, of Warsaw, has made another contribution to the almost endless literature of the deep perineal muscles, which he has studied both by dissections and by microscopic sections. His results strike us as essentially similar to those of Holl, especially if we bear in mind that great regularity is not to be expected in the complicated web of fibres that surround the membranous urethra. Thus, although the work is undoubtedly good, we should hardly have noticed it had it not been for the part relating to the veins of the penis and to the mechanism of erection.

Dr. Tschaussow's experiments lead him to deny the old theory that these muscle serve "*ad refluentem sanguinem retardandum.*" He satisfied himself that the *tendinous* origin of the deep transverse perineal muscle is pierced by several of the *venæ profundæ penis.* He found that the plexus of Santorini has but little connection with the dorsal vein of the penis, depending chiefly on the internal pudic veins; which is quite opposed to Henle's statements. He found further that veins from the bulb of the urethra join the hæmorrhoidal plexus, and that the blood spaces in the corpus spongiosum and the corpora cavernosa communicate by short thin veins running between the latter and opening into the dorsal vein. The study of microscopic sections convinced him that few and small veins pierce the muscular layer, and that the rich plexus around the bulb runs chiefly into the trunk of the internal pudic and into the hæmorrhoidal veins. Thus the contraction of the muscles can have but little effect on the circulation.

The author made injections into the penis with the following results: An injection into the corpus cavernosum did not enter the corpus spongiosum nor the dorsal vein. An injection into the corpus spongiosum filled the dorsal vein very quickly but very little or none entered the corpora cavernosa. An injection into the peripheral end of the dorsal vein, however, filled both the corpora cavernosa and the corpus spongiosum.

The last of these injections demonstrates the communications between the dorsal vein and the other systems. If, therefore, when the corpora cavernosa are injected the vein remains empty it shows, according to Tschaussow, that the distended spaces compress the venous radicles, and this he believes is what occurs in erection. We hope the subject will receive further attention, for, convincing as these arguments appear, we are slow to accept views directly at variance with those of Henle.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

FEBRUARY 25, 1884. The President, DR. CHARLES D. HOMANS, in the chair.

ANURIA FROM COMPRESSION OF THE URETERS BY CANCEROUS DISEASE.

DR. MINOT showed the specimen, which was taken from a woman fifty-three years old, who entered the Massachusetts General Hospital February 13th, and died February 21st. She was a widow; never had children or miscarriages. For about three years she had occasionally observed slight discharges of blood from the vagina. For the past six months there had been slight leucorrhœa, soreness above the pubes, frequent micturition, and occasional painful defecation. For four weeks there had been great thirst, polyuria, and itching of the arms and of the anus. She had lost much flesh and strength, but had been in bed only nine days. She was anæmic and sallow. Temperature 99.8° F., pulse 120, respiration 26. On the 14th she passed sixteen ounces of urine in twenty-four hours. This was examined by Professor Wood, who reported it as pale, specific gravity 1008½, neutral, a slight trace of albumen, very large excess of bladder and vaginal epithelium, and also clumps and isolated large spindle-shaped and caudate cells, suggestive of morbid growth, a little blood and pus. On the 15th one ounce of urine was drawn by catheter, and from that time, during the remaining six days of her life, the patient passed no urine, except about two drachms with a dejection on the 18th. She vomited everything taken, and her breath had a urinous odor. The vomitus of the 20th, also examined by Professor Wood, was found to contain 6.7 grammes of urea to 912 cc. There was pain in the right flank. She retained consciousness to the last, although drowsy much of the time.

The autopsy, made by Professor Fitz, showed that the enlarged uterus filled the pelvis, and was adherent to the bladder and rectum and to the pelvic walls. The

bladder contained half an ounce of turbid urine. On its posterior wall was an ulceration three quarters of an inch in diameter. The uterine cavity was four inches in depth; the os externum readily admitted the forefinger. The substance of the uterus was transformed into a uniformly opaque, white tissue, from which on pressure sebaceous-like plugs were squeezed. This change extended to the fundus, where there was a round, laminated nodule, easily crushed, but with no sebaceous-like plugs. The left ureter was dilated and tortuous, and obliterated for an inch and a half at the vesical end by means of a soft gray new formation. The left kidney formed a sacculated tumor of the size of the fist, only a thin seam of renal tissue being left. The right ureter was dilated, the vesical opening was of the size of a pin, and the course of the vesical end tortuous. The right kidney was half as large again as the left, its surface grayish-white, the cortex easily detached, increased in thickness, anæmic, not opaque; tubular regions indistinct; pelvis moderately distended. Lymph glands over promontory of sacrum enlarged to the size of an English walnut; on section white, and homogeneous, and numerous sebaceous plugs were squeezed out on pressure.

An interesting feature of the case was the diagnosis of morbid growths by means of the microscopic examination of the urine; also the evidence of the partial elimination of urinary constituents by the lungs, and probably also by the mucous membrane of the stomach. The preservation of consciousness along with urinary suppression is remarkable, but not very unusual. Dr. Minot had before reported to the Society a similar instance. The treatment consisted mainly in the subcutaneous injection of pilocarpine, in the hope of relieving the kidneys through vicarious action of the skin. Dr. Minot showed two microscopic specimens kindly prepared by Dr. H. F. Vickery; one was taken from the enlarged glands in the lumbar region, and the other from the uterine tissue. They showed the characteristic alveolar structure of flat-celled cancer.

DR. GEORGE F. JELLY read a paper on

CASES OF GENERAL PARALYSIS OF THE INSANE.[1]

DR. EDES said that while the diagnosis of general paralysis was, as Dr. Jelly had stated, undoubtedly easy when characteristic mental symptoms accompanied, as in the cases reported, the bodily paralytic manifestations, he wished that Dr. Jelly had spoken more in detail of cases in which the diagnosis was difficult, and especially with reference to the possibility of the disease beginning and continuing for some time without delusions or melancholia.

He referred to the case of a man who had been rather a free liver, and whose general health rather deteriorated until he had a slight attack, characterized by a temporary aphasia and a just perceptible hemiplegia. He became better and worse, and again had a similar attack. His speech was indistinct, and his lips trembled, but there had never been any delusions whatever, and no greater melancholy than might be expected in a man who fully realized the seriousness of his case. He was rather inclined to be emotional, and often seemed ready to weep. His patellar reflex was exceedingly well marked, and there was ankle clonus.

Dr. Edes would like to hear the opinion of Dr. Jelly and Dr. Folsom as to this being a case of general paralysis.

[1] See page 217 of this number of the JOURNAL

DR. JELLY stated that he intended saying in the paper that the diagnosis is easy when we have all the peculiar symptoms named, but that it is sometimes quite difficult. Mental symptoms generally precede those of muscular impairment. Where they do not he would await developments before making a positive diagnosis.

He did not mean that the post-mortem appearances which he described were found in all cases, but he thought those given were the ones most commonly found. There are none that are absolutely pathognomonic, so far as he can learn.

DR. J. O. GREEN read a paper on a case of

INFLAMMATION OF BOTH TYMPANA AND BOTH LABYRINTHS IN SCARLET FEVER.

A girl aged ten years, never very strong, and who a short time before had an ill-defined illness, the diagnosis of which could not be ascertained, was seized fourteen days before with vomiting and other symptoms which developed a scarlet fever. For the first week the disease was not severe, and two brothers at the same time had the fever of a mild type. About the sixth day she was noticed to be deaf, and just before this spoke of very loud noises in the ears. In two or three days the deafness became total; no sound of other voices could be heard, nor her own, and the watch was heard neither on the ear, skull, nor when held between the teeth. At the same time the fever became very severe, and for several days the condition was such as to give much anxiety; there was no active delirium, and but very little complaint of pain in the ears. On the tenth day a discharge began from the left ear, and soon after from the right; this was composed of thin, very abundant clear serum, with a slight admixture of flakes of apparent pus. On the eleventh day the violence of the fever rapidly abated, the appetite returned, but the deafness remained the same. Throughout the disease the mucous membrane of the nose and pharynx was but moderately affected, and the tongue was never of the intense red so often seen.

On the fourteenth day of the fever, the ninth day from the beginning of the deafness, and the fourth or fifth day from the appearance of the discharge from the ears, I saw her in consultation on February 17, 1884.

Desquamation of the hands was just beginning; paresis of the left facial nerve was marked. Both meatuses were slightly excoriated by the discharge; each concha was filled with clear, limpid serum, which was removed with the syringe, as were also several large flakes of epidermis from the meatuses.

The left ear was inspected, but only a red mass of swollen tissue could be seen, without any of the usual landmarks. After thorough drying the serum was secreted so rapidly that but a momentary glimpse could be obtained. In the right ear was a similar mass of red swollen tissue, in the centre of which the manubrium of the hammer could be seen distinctly, and on the posterior wall of the meatus close to the tympanic ring were granulations bleeding to the touch. By Politzer's inflation no impression could be made on the ears. The child was then rapidly etherized in order to thoroughly explore and cleanse the tympana. In the left ear no traces of the membrana tympani or ossicles could be found, and the whole inner wall of the tympanum was distinctly carious. In the right ear the whole membrana tympani was gone, the swollen tissue was

the inflamed tympanic mucous membrane, and the hammer was in its normal position but completely dissected out by the sloughing which had occurred. Both Eustachian tubes were catheterized, and the air passed freely with distinct whistles into the meatuses. The operation lasted scarcely five minutes, and the child came out of the ether rapidly and well with but slight nausea. Thorough douching with warm carbolic solution three times a day and Politzer's inflation once a day were advised.

The case is interesting in several ways: First, from the involvement of both labyrinths as shown by the total deafness, the labyrinthine disease evidently occurring within two or three days of the first ear trouble, and probably being an inflammation secondary to the inflammation of the tympanum and an extension inwards of that inflammation; secondly, from the extensive caries which already existed on the ninth day after the first noticeable deafness.

Two or three other points are worthy of attention: Very loud noises were complained of before the deafness was noticed; in this case no description was given of them, but when loud "clashing," "ringing of small bells," or distinctly "musical notes" are heard during scarlet fever or cerebro-spinal meningitis, they are very apt to be the immediate premonitions of labyrinthine disease, whereas the subjective noises always accompanying acute purulent inflammation of the tympanum are described as "hissing," "singing," "buzzing," or "throbbing." In this case it will also be seen that the development of the ear-disease was accompanied by a great increase in the fever, and, in the absence of other reason, might be regarded as its cause, especially as the first discharge from the ears was followed the next day by a rapid abatement of the fever and of all the dangerous symptoms. The discharge in this case was almost entirely clear, limpid serum and the secretion more rapid than I have ever seen it. The usual serum of tympanic inflammation is wine-yellow; this was nearly as clear as water. In thinking of the case since, I fear that this may be a most serious symptom as indicating destruction of some of the membranes communicating with the labyrinth, and that the liquid is an escape of the labyrinthine peri- and endo-lymph. The few cases in which this has occurred, and of which I have seen one, show that the secreting power of the labyrinth is enormous, considering its size; all of these cases, however, with which I am familiar, were cases of injury, and not of inflammation.

The only means of differentiating labyrinthine fluid from the serum of an inflamed mucous membrane would be a chemical analysis which would show the absence of albumen in the labyrinth water.

The paresis of the left facial was undoubtedly due to the inflammation and caries of the left tympanum which had affected the Fallopian canal.

To a question by Dr. Minot, Dr. Green said that we have severe cases of disease of the ear in which the scarlet fever is light. On the other hand, severity of the disease by depressing the patient tends to enormous sloughs.

— A high official of England has resigned his post for the reason that while he had always hoped to die in office, he finds his failing health forbids. Such health as forbids one's dying is not so bad after all.

THE NEW YORK ACADEMY OF MEDICINE.

THE DIFFERENCES IN FORM OF THE ADULT HEAD.

At a meeting of the Academy held February 21st, Dr. John C. Dalton made an address on the above subject. A short time ago, he said, he had become interested in the method of comparing the differences in the adult human head which was afforded by the machines which hatters were accustomed to use for getting the exact size and shape of the heads of their customers at the level at which the hat was usually worn. He had secured a great variety of paper patterns representing different heads, and had been furnished with no less than 360 of these from one hat shop in New York. According to their shapes the heads were divided into medium, long, and round, heads. One hundred being taken as the standard of width, if the length were between 120 and 130, the head was a medium one; while if the length was under 120, it was a round one; and if over 130, a long one. In addition, the heads varied greatly in regard to the comparative width of the back and front parts and the symmetry of the two sides. Some, again, were perfectly curvilinear, while others presented angles and straight lines at some points.

Dr. Dalton now called special attention to eight of the paper patterns to which he had referred, which he had had hung side by side upon the wall. The first was regular in shape, presenting a curvilinear and comparatively symmetrical oval, which resembled in its general outline the section of an egg. The second presented a squaring of the front part of the head, there being a decided flattening of the temples. In many individuals there was actually a hollowing out of the head at the temples. In the third the square front was still visible, but the occiput was not rounded, as in the other two, but somewhat elongated. Consequently the long head was beginning to appear, instead of the medium, and in this instance the length was 135. In the fourth the extreme of elongation among all the heads whose outlines were taken was reached, namely, 153. In the fifth pattern, however, there was noted a round head, which was tolerably symmetrical, and had the proportion of 108 to 100 in its diameters. In the sixth the length was 117, and here the occiput was seen to be wider and the front part of the head narrower than in the others. Number seven was remarkable as being the most unsymmetrical of all, and in number eight the length was 128, while there was a very broad occiput.

The want of symmetry was one of the most prominent characteristics in almost all of them; although this was not always evident at a first glance. If, however, the pattern were doubled upon itself, the difference between the two sides at once became apparent. When this test was applied to all in turn, number six was found to be the most nearly symmetrical. Want of symmetry, then, was the rule; and the same thing, Dr. Dalton said, was true in regard to the brain. He had never yet met with a head or a brain that was perfectly symmetrical. In addition to other variations, the cerebellum was almost always more or less twisted as regards the axis of the cerebrum. But this was not surprising when it was remembered that no human face was symmetrical. Among other matters of interest connected with this subject was the fact that these diversities in the symmetry of the head were always in one direction. There was almost invariably a decided

preponderance towards one side, which gave the head a certain amount of obliquity. Thus, if the occiput were flattened on one side, the temple would be found to be flattened on the other. In several cases a twist towards the left side was noted, and in nine out of twelve instances in which the head was perceptibly twisted the obliquity was towards the left, while in only three was it towards the right.

This seemed, at all events, to be true of heads in New York, and here there was also a decided preponderance of the long head. Dr. Dalton had found that sixty-four per cent. of the heads studied were medium, or with a long diameter between 120 and 130; ten per cent. round, or with a long diameter under 120; and twenty-six per cent. long, or with a long diameter of over 130. Consequently the long heads outnumbered the round ones in the proportion of two and a half to one. These differences between the two sides of the same head and between different heads were of interest also in connection with the hypothesis which was at the present time pretty generally accepted, that all parts of the brain did not have the same functions. The doctrine of cerebral localization recognized that the gray matter in some parts of the brain performed different nervous actions from that in other parts. There were motor centres and perceptive centres, and it was believed that this difference in function was connected with a difference in structure, the cells of the motor tract, for instance, being different from those of any other part in character and arrangement. From the external examination of a long head it might very naturally be supposed that there was a larger amount of gray matter in the cerebral substance than in a round one, because a long oval presented a surface of greater extent than a short one. This might, indeed, be true if the external surface of the hemispheres were smooth. On the contrary, however, we knew that the cortical layer of brain tissue was not smooth, but convoluted, and in the brain contained within a round cranium the fissures might be deeper and the foldings more numerous and complex than in one belonging to a long head. The shape also varied in other ways, as, for instance, a round head might be much deeper than a long one in a vertical direction, and, therefore, we could not conclude that because a head was round and compact the brain contained less gray matter than in the case of a long one. Still, again, the motor centres in two brains might be precisely the same in structure while the fissures might be deep and narrow in one, and shallow and broad in the other, so that there might be exactly the same amount of gray matter in the two, though their forms were entirely different.

These points were worthy of consideration, he thought, when it was remembered what differences in form might be due purely to external causes. In certain tribes of Indians it was well known that the head was compressed during infancy, and retained the distorted shape thus given it throughout life. Among the Chenook Indians the front part of the head was thus compressed, and among the Natchez the back part, yet as regards function there was no difference whatever between the brains in the two forms of heads.

DR. BARKER said that some fifteen or twenty years ago a great many papers had been written in the obstetrical journals in regard to the influence of parturition in forming the shape of the human head, and in connection with this subject he had instituted a series of inquiries in the lying-in department of Bellevue Hospital. The shape of the head immediately after birth and then again eight days later was noted by the members of the house staff in 132 infants during a service of nine or ten months. Dr. Barker then alluded to the compression, moulding, and change of shape which the head underwent in passing through the pelvis, especially in tedious labors, and said that in the case of left occipito-anterior positions of the vertex there was almost always a pressing out of the head towards the right on account of the space existing in the right oblique diameter of the pelvis, which permitted it to protrude in this direction, while in right occipito-anterior positions the bulging was towards the left. In consequence of this he could almost invariably tell simply by examining the head of a new-born infant, if he saw it within forty-eight hours after birth, whether the head had presented towards the left or the right. This applied only to anterior positions of the vertex, however, since in posterior positions the shape of the head was much changed by the rotation which it had to undergo. At the time referred to the question was discussed a great deal as to whether this compression during labor influenced the shape of the head permanently, and as to whether it affected the functions of the brain in after life. In the observations made at Bellevue Hospital it was found that the disproportion between the two sides of the head had almost always entirely disappeared by the end of the eight days, but in some instances this was more or less prolonged. There was another point to which he should like to call attention. If Dr. Dalton, ten years from now, were to present the outlines of the same heads, the diagram of which he had exhibited this evening, would they be precisely the same as at the present time? For himself he felt pretty sure that the form of the head changed more or less in adult life, and even at quite an advanced age, and this belief was founded on the fact that his hatter had found that his head had varied somewhat in shape from time to time.

DR. J. LEONARD CORNING thought the paper of deep interest. The ideas that pressure upon a certain part of the head did not result in dwarfing and atrophy of the organs beneath, but simply in pressing them into a different location, and that form had not so much to do with the functions of the brain as the amount of surface presented by the gray matter, were certainly well worthy of consideration. As to the question of asymmetry, this was a point which had of late often been brought up in criminal trials to prove that the brain of the prisoner was not well balanced, especially in the case of Guiteau. Arguments to this effect based on the asymmetry of the head he believed were not supported by facts, and the investigations of Dr. Dalton showed that notwithstanding such extreme distortion as was caused by the custom in vogue among the Indians referred to the organs were preserved intact.

After a few remarks by Dr. David Webster, DR. DALTON said that the idea of changes occurring in the adult head was entirely a new one to him, but as it was a well-known fact that other parts of the body changed very materially as life advanced, he did not see why this might not be the case with the head also. The twist of which Dr. Barker had spoken as occurring during labor no doubt disappeared, as a rule, shortly after birth; but in a few instances this obliquity probably remained permanently. As the result of his in-

vestigations he would say that we could not conclude from the existence of asymmetry in the cranium that there was a corresponding want of symmetry in the brain itself.

DR. P. ALBERT MORROW then read a paper on

AN IMPROVED METHOD IN THE TREATMENT OF CERTAIN FORMS OF SKIN AFFECTIONS.

The method referred to was the application of various medicinal substances by means of fixed, adhesive dressings, such as collodion, gelatine, and gutta percha, which has received so much attention from dermatologists during the last one or two years, and the paper was discussed by DRS. BRONSON, J. C. JACKSON, and SHERWELL.

FIRST AID TO THE INJURED.

Before adjournment DR. W. M. CARPENTER presented a resolution, which was adopted, giving the indorsement of the Academy to the Society for Instruction in First Aid to the Injured, which has been in existence for two years in New York, and which now proposes to extend its work to other parts of the country.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

AT a stated meeting of the Society held February 25th DR. WILLIAM S. HALSTED read a paper entitled

THE EFFECTS OF ADDUCTION AND ABDUCTION ON THE LENGTH OF THE LIMB IN FRACTURES OF THE NECK OF THE FEMUR,

in which he contended that adduction or abduction always formed an important element in the length of the limb in these fractures, and that all statistics of measurements in which they were not taken into consideration were worthless.

The paper was discussed by DRS. A. B. JUDSON and JOHN A. WYETH, both of whom believed it was impossible to secure such exactness of measurement as the writer aimed at, and that the matter was not of as much practical importance as he claimed.

DR. E. C. SPITZKA then read a paper entitled

PATHS OF COÖRDINATION,

based on a case of pure unilateral ataxia without paralysis, which had been under his observation for several years, and in which there was found at the autopsy a secondary degeneration of the stratum intermedium, commencing about the lower third of the pons Varolii, just to the right of the median line, and crossing below the pyramids to the left side, where it extended for some distance down the cord. The symptoms and lesions were described with great minuteness, and the writer believed that the case threw a great deal of light on the tract concerned in the transmission of coördinating power.

The paper was discussed by DR. E. C. SEGUIN, who thought that the results of physiological experiment were somewhat at variance with the conclusions of Dr. Spitzka.

COLLECTIVE INVESTIGATIONS.

DR. DAVID WEBSTER, chairman of the Committee on the President's Address, reported that the committee had decided to recommend the carrying out of the President's suggestion in regard to collective investigations. They believed, however, that all abstruse subjects should be avoided, and only those considered which were of interest to every member of the profession. Intestinal obstruction was proposed as the first topic, and they recommended that to each member of the Society a printed slip should be sent by the secretary, requesting him to send in replies to the following questions, and to be present at the meeting of March 26th, when the subject would be publicly discussed: (1.) How many cases of intestinal obstruction have you treated, and what peculiar symptoms were manifested in each case? (2.) Have you ever performed an operation for the relief of intestinal obstruction due to peritoneal adhesions, and if so, what was the result in each case? (3.) Have you treated any cases of intestinal obstruction, partial or complete, where the so-called pathognomonic symptoms, such as stercoraceous vomiting and obstinate constipation, were absent? The recommendation of the committee was adopted.

THE REPORT OF THE DELEGATES TO THE STATE MEDICAL SOCIETY

was made by their secretary, DR. DANA, who announced that three of the delegates had been elected permanent members of the State Society, namely, Drs. Lockrow, Gibney, and Lewis.

DR. A. JACOBI, from the Committee on Hygiene, moved that the Society should give its official indorsement to

THE CHILDREN'S FACTORY BILL,

now pending in the Legislature. Adopted.

LICENTIATES IN MIDWIFERY.

DR. P. C. COLE read the drafts of two bills which were to be brought before the Legislature, and moved that a resolution be passed to the effect that the Society approved of their general intent and object. The first was to incorporate the New York Maternity and School of Midwifery, for the instruction of women in midwifery and the giving of general clinical instruction in this department of medicine. The second was for the purpose of regulating the practice of midwifery in the State of New York. It provided that no person should practice midwifery unless a duly qualified practitioner of medicine or else a licentiate in midwifery. Licentiates in midwifery were required to receive at least six months' instruction and pass a satisfactory examination; though licenses could be granted also to such practicing midwives as should obtain a certificate from the Board of Managers of the New York Maternity and School of Midwifery. The penalty for infringement of this act, which was to be classed as a misdemeanor, was a fine not to exceed $1000. After some discussion, the whole matter was referred to a special committee of five, who were requested to report at the next meeting of the Society.

— A correspondent writes: "One man may steal a horse, while another may not look over a hedge; for example, the city may put heaps of unmixed salt over the numerous air or water covers in the streets (thereby causing holes in the ice, which endanger the lives and limbs of horses and their drivers, in addition to the other effects of salt), while a railway company may not put sand containing a fraction only of salt on their tracks without lawsuits and fines. Here 's official consistency for you!"

Recent Literature.

Voice, Song and Speech. A Practical Guide for Singers and Speakers from the Combined View of Vocal Surgeon and Voice Trainer. By LENNOX BROWNE, F. R. C. P., Ed., and EMIL BEHNKE. With numerous Illustrations by Wood Engraving and Photography. 323 pages. New York: G. P. Putnam's Sons. 1884.

There are few subjects which offer so many conflicting opinions as the questions relating to voice production. The volume before us, besides containing some original matter in regard to the formation of the registers of the voice, presents the views of one school, — in our judgment the correct one, — and is the joint work of a vocal surgeon and a vocal trainer, whose experience had convinced them "that wrong production of voice or abuse of its functions was the chief cause of most of the cases of vocal failure and even of throat disease," and "that the scarcity of fine voices generally acknowledged to exist was due less to dearth of material than to faults in its cultivation and exercise." The two chief faults are (1) attempting to use the voice with an insufficient amount of air or with imperfect control over the respiration, and (2) an undue forcing of the registers. How to avoid and correct these faults is explained in the chapters on the Hygienic Aspect of the Vocal Apparatus and on Voice Cultivation. These chapters consider in detail all the points bearing upon the care and preservation of the voice, and express the views generally held at present of the true methods for good voice production.

A voice register is defined as "a series of tones produced by the same mechanism," and the five registers into which the authors divide the human voice as a whole they claim are each produced by a distinct muscular mechanism.

The photographs of the larynx taken in the act of singing represent the glottic chink and the position of the vocal bands as they must always exist in the production of the respectively produced vocal tones. It is this portion of the book which relates to the photography of the larynx and soft palate which is of most interest to medical readers. The difficulties of photographing an object in such constant motion and so hidden from view as the larynx have at last been overcome, and the results contained in this volume are the most satisfactory of any yet obtained. One of the points brought out was the difference between the appearance of the arytenoid cartilages as seen in the photograph and that of the conventional image we are accustomed to see in books. This consisted in double outlines in the photograph, which were first considered to be a blemish, but was afterward determined to be due to the perspective view of the interior surfaces of the arytenoid cartilages.

Two photographs taken in the act of singing show the positions which the vocal bands assume in the upper thick and falsetto registers. In the "upper thick" they are approximated and everything is contracted, while in the falsetto the rima glottidis is open and all parts are loose and lax. The appearances in the other registers of the voice are represented by engravings. On ascending the scale and coming to the "thin" register there is nothing in the position of the vocal bands to distinguish the "thick" from the "thin" register. But by illuminating the larynx through the throat with a powerful light, as was done by Czermak, and then examining with the laryngoscope, it would seem that the vocal bands are in the "thin" quite transparent, while in the "thick" register they are opaque and bulky, "a difference brought about probably by a contraction of the vertical bundles of the thyro-arytenoideus externus." For the production of tones in the "small" register — the highest part of the soprano voice — the mechanism "consists in the formation of an oval orifice in the front part of the glottis which contracts the more the higher the voice ascends, the vocal ligaments being, in the hinder part, pressed together so tightly that scarcely any trace of a slit remains. No vibrations are here noticeable, while they are, on the contrary, so very marked in the anterior portion as sometimes to blur the outlines of the orifice to a considerable extent." The authors claim to have seen these appearances repeatedly in women as well as in boys. We regret that a photograph of this condition of things was not produced instead of the well-finished engraving which accompanies the text. Interesting and suggestive as are the authors' remarks in regard to the different ways the vocal bands arrange themselves to produce the different tones, we doubt if they will be accepted until verified by a large number of observations upon different individuals.

The series of photographs of the soft palate show the positions it assumes in the production of tones differing in pitch and quality. It rises with the ascending scale, and the quality of the voice depends upon the degree of tightness with which it closes against the posterior pharyngeal wall. In singing a high note with a pure quality the uvula contracts, the arch between the pillars of the fauces becomes higher and narrower, and the closure of the palate with the back of the pharynx is complete, while on producing the same note with a nasal quality the soft palate is relaxed, thereby allowing the passage of air through the nares, upon which the peculiar quality depends.

We agree with the authors in believing that their results should effectually silence objections to amputating the uvula or removing the tonsils when they interfere with the free action of the soft palate, which, as these photographs clearly demonstrate, is so important for good voice formation.

The book is written in a popular style, and is intended to be a complete manual for singers and speakers. As such we can recommend it as a safe and valuable guide.

A System of Human Anatomy, including its Medical and Surgical Relations. By HARRISON ALLEN, M. D. Section V. Nervous System. Philadelphia: Henry C. Lea's Son & Co. 1883.

This volume confirms the high opinion we have already expressed of this work, and, moreover, strengthens our conviction that it is suited to the wants of the graduate rather than of the student of medicine. The anatomy of the brain is a most difficult matter to present, and we think that the distinguished author has been very successful, always with the reservation implied above, that the reader should be prepared by previous knowledge. It seems to us that the important subject of cerebral localizations in the cortex is rather lightly touched upon. We find nothing whatever of the relations of the convolutions to the skull, a very important chapter, which we hope will have a place in

the final section of the work. The arachnoid is well described as separating the subdural and the subarachnoid lymph-spaces. The treatment of the peripheral nerves is very satisfactory. We are glad to find that the author recognizes twelve cranial pairs. The remarks on each nerve are very interesting, and contain much that is of practical value. Indeed, they constitute one of the charms of the book. The illustrations are good, but we own we should like to see a number of diagrams, which would help greatly in elucidating the anatomy of the brain. The volume offers throughout new instances of the learning and care of the author.

T. D.

Medical and Surgical Journal.

THURSDAY, MARCH 6, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE RELATION OF LABORATORIES TO MEDICAL SCIENCE AND MEDICAL EDUCATION.

THE recent opening of the new biological laboratory of the Johns Hopkins University and the address then delivered by Professor Martin, in which he traces the rise and development of the laboratory as a revolution in and an aid to study within the past sixty years, and delineates somewhat the just expectations from the expansion of laboratory work in the future, offer an occasion which we must not neglect, to say a few words as to the relation of laboratories to medical science and medical education, especially as in a previous editorial we dwelt particularly upon the necessity of preserving the relative importance of clinical study pursued largely by laboratory methods, by methods yielding first-hand and not second-hand knowledge.

If our age in the world's history deserve any adjective at all it surely deserves the adjective progressive, and as we are in this age we also must be progressive, for the part may not rebel against the quality of the whole. Assuredly medicine has progressed, but to be with the time it must continue to advance higher and further. Now our advance as a profession depends very largely upon the teaching we get while students, for it is a matter of current observation that the active practitioner gradually falls behind as he grows older, his point of view is supplanted by a newer and better one, and he retains his preëminence only on the score of experience, which gives to his opinions a value which nothing else can insure. The practitioner may begin fully abreast with the knowledge of his time, freshly imparted to him by specialists, but he cannot remain abreast and practice too, and it is this which makes it a vital necessity to educate medical students to the highest medical level possible, for they will not rise with the elevation of medical science, save in rare exceptional cases. We must be honest about this, and conform our plans to the inevitable.

Let us admit, then, the antagonism between active practice and thorough acquaintance with the progress of medicine, and from this admission let us deduce the duty of educating medical students to the highest limit possible; it then still remains for us to decide how we may best fulfill our acknowledged duty. Now medicine is a scientific study, and in the methods of scientific teaching a vast improvement has taken place chiefly within the last quarter of a century. It has been recognized that the sciences deal with the things and occurrences by which we are surrounded, that a description of these facts by another does not constitute real knowledge, but that we know and can know only at first hand. The student must be brought face to face with the phenomena he is to study, he must have a personal acquaintance with the means by which a scientific law is demonstrated, and accordingly laboratories have been established for the instruction of students, at least in all the natural sciences. In these laboratories the student may make acquaintance with the facts and phenomena of nature. What is true of science at large holds also true of medical science; the chief improvement made in our time has been to secure to the student more direct and immediate contact with the facts of medicine; he works more in the dissecting room and physiological laboratory, and should also spend more time at the bedside of the sick. All our readers will doubtless acknowledge the value, or more than value, the imperative necessity of the most thorough and extended clinical instruction possible, and, as before said, we have recently had occasion to insist upon the importance of clinical teaching to the medical student. The clinics, with small classes, give of diseases that first-hand knowledge which laboratories afford of other departments; and, indeed, from this point of view the distinction commonly made in medical schools between laboratory and clinical instruction cannot be justified, where the term clinical is properly applied, however natural it appears as a matter of convenience. Nevertheless, for our present purpose, we accept the distinction, and wish to say a few words concerning the medical laboratories in the restricted sense.

The modern laboratory is a new thing, the invaluable culmination of that immense intellectual revolution which has nearly freed us from the thraldom of dead authority. Indeed, the progress of scientific education may be approximately measured by the number and character of the laboratories at its disposal. There is no more hopeful indication of the gradual elevation of our medical schools than is given by the improvement and multiplication of their laboratories. For a long time the anthropotomic laboratory, as Dr. Holmes with characteristic aptness has named the dissecting room, existed alone; all the other departments relied solely upon didactic instruction. Only in anatomy

did the students get that direct practical training which was lacking in the other so-called scientific branches of medicine. At present new laboratories are organized from time to time, and especially for chemistry and physiology have many been recently formed. But even the best of our schools are still distant from the goal which must be attained before they can fully respond to the demands of thorough education, because each of the medical sciences needs its own laboratory, and until they are all provided for the goal will remain beyond reach. Anatomy may be granted the first claim, but the other claimants press quickly after it; physiology, chemistry, histology and embryology, pathology, experimental pharmacology, and hygiene, not one of them can do its best without its own large and expensive laboratory. We trust that it cannot be many years before every good medical school in the country will possess laboratories at least for physiology, pathology, and hygiene. For our own part we believe that hygiene is most unfortunately neglected in this country, and that no other addition to the current curriculums of our medical schools is so urgently needed as that of hygiene.

Our medical schools ought, however, to do something more than turn out so many diplomaed students per annum. Those, to be sure, that are carried on as commercial speculations for the financial benefit of the members of the Faculty, cannot be expected to sacrifice their profits to ideal aims, but the endowed schools ought to contribute to the promotion of medical knowledge, and offer ample facilities and hearty encouragement to investigators. In organizing their laboratories these latter schools should bear this higher duty in mind. The improvement of medical practice depends more largely than is perhaps commonly believed upon purely scientific researches, and it is indispensable to wise forethought to have in mind the duty of offering to those young men, who have the inclination and capacity, the opportunity to become investigators after a course of thorough training. This higher duty may be the more readily fulfilled because experience has amply demonstrated that instruction and investigation may be successfully and economically combined in one laboratory.

A good scientific laboratory, properly equipped for its double functions, is a far greater, more difficult, elaborate, and costly enterprise than is generally conceived. The fittings are necessarily numerous, varied, and expensive, even in those departments which need the very least; considerable space is required for the storage of the apparatus, and plenty of space and light for work, — we never heard of a laboratory that had too much room! The character and value of the laboratory will, however, be determined more by its officers than by all else, a fact amply exemplified by the first inspirations and the earlier work of the generation of physicists and biologists now passing off the stage. Perhaps we cannot better express what the officers should be and do than by the following extract from a recent editorial of *Science* upon laboratories: —

"The highest officer must be the responsible director, — a man of superior ability, extensive attainments, and prolonged experience; one, in short, who has mastered his department of science, knows its possibilities and deficiencies, and is, therefore, capable of judging what work is most feasible and instructive for students, and what problems are best adapted for investigation. It is sheer waste for a man of such high capacity to sacrifice his whole time to the arrangement of apparatus or the preparation of experiments for his lectures or his students; therefore it is desirable, we prefer to say indispensable, that he should have an assistant, preferably a young devotee of science, who will be fitted by his experience as an assistant to ultimately become himself director of a similar laboratory. The third person is the laboratory keeper (*diener*), who needs must be a man of some mechanical skill, so that the precious instruments may be safely intrusted to his care. He should be something more than a servant, and less than an assistant. A laboratory without this working force cannot do much for the promotion of science, although even more modest ones may be valuable for simple instruction. A first-class laboratory, and in Germany are many such, has always a larger number of officers. There are few persons among us who appreciate the magnitude of a scientific laboratory; were it otherwise there would not be so many petty substitutes for them."

A laboratory conformed to the high standard set must spend much money; therein lies the difficulty which prevents the immediate establishment of such, for our medical schools are not at all or insufficiently endowed, and have not the means wherewith to create the laboratories, however eagerly they may desire them. If there be any one who wishes to confer a great benefaction upon medicine and mankind by an endowment we should be very glad to see such a gift made for the support of a first-class laboratory at one of the accredited schools already existing.

Medicine, which is exclusively devoted to human welfare, has received in return but little from the generous in comparison with the liberal amounts bestowed for other purposes. The best form of gift would be without restrictions, but if the donor prefers to designate a special object his wisest choice, in our belief, would be, if the sum is *very large*, to found a hospital under the control of a first-rate school, or, if the sum is smaller, to endow a laboratory of physiology, hygiene, pathology, or histology, or such branch as he may elect, a biological institute being thus ultimately evolved.

PERIODICAL CHANGE OF COLOR OF THE HAIR.

A curious and apparently unique case of periodical change in the color of the hair is described by Dr. C. Reinhard in the last number of *Virchow's Archiv*. The subject exhibiting this interesting phenomenon was a female epileptic idiot, thirteen years of age, who was under careful observation at the Dalldorf-Berlin Asylum for two years. Very shortly after the reception of this girl at the asylum it was noticed

that her hair, which was soft and thick, changed its color from time to time from a light yellow to a deep red, and back again. The process, beginning at the end of the hairs, was accomplished pretty rapidly — in two or three days, and each change remained seven or eight days. It was noticed that the changes of color were, in a general way, synchronous with the periodical changes in the psychical condition attendant upon the epileptic attacks, the dark color being assumed during the time of excitement and the lighter color during the succeeding period of stupor. These changes occurred in the same hairs, not being dependent upon the growth of new hair. There was no disease of the hair, nor of the scalp other than a slight dryness during the periods of stupor.

The writer, as the result of a careful consideration of this case from different points of view, supported by a thorough microscopical examination of the hair at various periods, and of the skin after death, advances as the most probable explanation of the phenomena described the occurrence of considerable and rapid changes in the amount of air contained in the hair shaft. The light color resulting from the presence of a larger quantity of air veiling the pigment, the darker color returning with the departure of the air. To these results the greater dryness and roughness of the hair, although slight, at certain times probably contributed in some degree by altering the refraction of the light, the drier the hair the lighter the color.

The presence of an abnormal quantity of air in the hair is the explanation offered for those cases in which a permanent and sudden change from dark to gray or white hair is reported, and notwithstanding Hebra's and Kaposi's dissent the occurrence of such is well established by Charcot, Bichat, Lélois, Raymond, and other trustworthy authorities, the last of these recording a case in which, apparently in consequence of severe neuralgia of the head, a patient's hair turned, in five hours, from black to white, passing through an intermediate stage of red. Landois describes one of these cases in *Virchow's Archiv*, April, 1866, and Wilson credits these sudden changes as authenticated. In these cases of permanent change some other influence than the mere increase of air must come into play, and it is probable that trophic nerve changes contribute to the result in the cases of sudden and permanent change, as also in the singular case of our author, the changes in the first class of cases being carried to an irreparable point.

The air may penetrate the hair shaft from the atmosphere or may have its origin from the gases present in the blood, and probably may be drawn from both sources. However acceptable these hypotheses may prove to account for the facts recorded, and in regard to which it would seem that there can be no question, the facts themselves may be fairly used to emphasize the following conclusions: (1) Trophic disturbances in the domain of the nerves supplying the scalp may accompany other cerebral phenomena; (2) these trophic disturbances may extend even to the hair; (3) such disturbances may, like many other nervous processes, assume a periodical character; (4) the attendant changes in the hair manifest themselves by a loss of color; (5) the same phenomenon also probably depends upon an abnormal storing up of air, and, as this case shows, may be transitory.

NEW NATIONAL PHARMACOPŒIA.

THE bill providing for the preparation of a new pharmacopœia, to which we referred in a late issue, attracts no little attention, and the comments are by no means favorable to the introduction of a new standard. The *Medical News*, of Philadelphia, returns to the charge, however, in a manner which does it little credit. It opens its last editorial on the subject as follows: "The proposition for a national pharmacopœia appears to meet with general professional commendation, and the only unfavorable criticism which we have seen is based on trivial grounds or on erroneous views of the power of Congress in the premises." As the only favorable comments are found in the *News* itself and the *Journal of the American Medical Association*, we fear that the *News* does not take great pains to learn the views of others. Whether the *News* acquaints itself with the views of others or is satisfied with its own is a matter of slight importance, but both the manner and the matter of its plea for the bill are noticeable. The editorial mentioned closes as follows: "The authority granted to that body (Congress) does not extend to fixing a standard of drugs and preparations which shall be imperative on the medical and pharmaceutical professions. It can, however, provide a standard for its own departments, and this is all that Mr. Randall's bill proposes to do. If, as is to be expected, that standard should prove free from the imperfections of the existing Pharmacopœia, the latter would be naturally superseded; but, in any case, it would be for the professions to determine which of the two should be recognized."

That is exactly the reason for the strongest opposition: Congress cannot fix a standard which is imperative on the profession, and as to the departments, we showed in a recent editorial that the existing Pharmacopœia had been already adopted by the Treasury Department, and by several States as a legal standard. Further action of this sort is easy, but in the choice between the professional and the proposed Congressional Pharmacopœias confusion must inevitably result.

The *American Druggist* makes the following contribution to history: —

"It is rather remarkable ... that, when Dr. E. R. Squibb proposed, a few years since, to change the method of organizing the Convention so as to place the revision of the work, practically, under the auspices provided for in the above act (Randall's bill), the leading opponents of the plan were Philadelphians, and that their principal effort was to show that the plan already in operation is the one to be preferred. The Convention of 1880 was called, and the subsequent revision was conducted accordingly; but the

Convention adopted measures which reformed the methods of revision and removed the control of the work from Philadelphia. It becomes, therefore, of interest to inquire whether the 'change of base' manifested in the 'City of Brotherly Love' can have any relation to the acts of the Convention of 1880."

MEDICAL NOTES.

— M. Perier, at l'Hôpital St. Antoine, has used for some years with good effect (*Journal de Médicine*, January, 1884) an aqueous solution of chloral, 1–100, for wounds involving the buccal cavity. The sedative action of the drug is added to its antiseptic effect. It should be employed after every ingestion of food, even of milk or bouillon, for the residue of such substances, undergoing fermentation, has an unfavorable action on the raw wound. In cases of fistulous tracts following necrosis the use of this solution by means of the irrigator is found to relieve all fetor, thereby increasing the appetite, and to have a prompt action on the pain and inflammation. Details are given of a gun-shot wound carrying away the whole of one cheek which healed very kindly under the chloral irrigations.

— Dr. Samuel Wilks, senior physician to Guy's Hospital, writes to the *Medical Times and Gazette* (February 9th) commending a recent paper by Dr. Matthews Duncan on Vicarious Menstruation and Amenorrhœa, and protesting against the belief in vicarious menstruation as an "old-wives' fable." He has never seen a case, and considers that the references to the subject in the text-books are a mere repetition of groundless traditions. He also declares against the use of the term amenorrhœa as referring to a substantive complaint. "For my own part," says he, "I know nothing of such a disorder, nor of such remedies as emmenagogues. I believe myself that amenorrhœa, like many other complaints, is the remnant of a popular delusion, and if so it should be eradicated, like the other disorder, from the medical minds.

— The London Society of Compositors has called the attention of the trade to the excessive mortality prevailing among the members of their craft. In the quarterly journal of the Union, *The Printer*, statistics are given concerning funeral allowances, which for the year amounted to seventy-four. Out of this number twenty-two compositors died from phthisis, and thirteen from bronchitis, etc., thus giving a total of thirty-five deaths out of seventy-four due to diseases of the respiratory organs. The causes to which this mortality is ascribed are the irregularity of the hours of work, and especially the lack of ventilation in the composing rooms. These things, however, do not seem sufficiently peculiar to the printer's trade to account for such a large mortality, nor do we know that as a class these workmen are personally especially careless. The limited figures given are not enough to base a general conclusion upon, and perhaps observation among American compositors would not show any worse results than among other in-door workers.

NEW YORK.

— The official report of the annual collection and distribution by the Hospital Saturday and Sunday Association for 1883 has just been published. The sum total of the collection was $42,803.69, against $30,681.52 the year previous, showing an increase of over $12,000. Of this, $27,040.50 was contributed by the churches and synagogues, and of this latter sum the Protestant Episcopal Church alone contributed $12,962. The Presbyterians came next, with $6,715.50, an amount just double that contributed by them in 1882. The Jewish synagogues gave $1,693.99, and the only other denominations giving over $1000 were the Reformed (Dutch) and Methodists. Sixty-nine Protestant Episcopal Churches contributed, against forty-nine in 1882; thirty-five Presbyterian, against seven in 1882; and thirty-seven Methodist, against seven in 1882. Ten thousand seven hundred and thirty-five dollars and sixty-eight cents was designated to particular institutions through churches and other sources, and the remaining sum (less about $3000 for expenses) was distributed to nineteen hospitals. Of these, the Mount Sinai Hospital gets the largest amount, $4,580.57, as affording the greatest number of days of hospital care for free patients for the year. The German Hospital receives $3,628.23, St. Luke's $3,323.14, the Presbyterian $2,321.82, and the Hospital for the Relief of Ruptured and Crippled $3,718.47.

CHICAGO.

— The graduating exercises of the forty-first annual course of lectures of Rush College were held at Central Music Hall on the 19th ult. One hundred and sixty-seven gentlemen received the degree of Doctor of Medicine. On Dr. A. L. Justice the honorary degree was conferred. Dr. Justice lives at El Paso, Texas, and is well and favorably known in the Western States, he having practiced for a considerable time at Denver, Col. Prof. Norman Bridge delivered the doctorate address at the commencement exercises. The alumni of the college, to the number of about four hundred, were entertained in the evening at a banquet given by the Faculty at the Grand Pacific Hotel.

— At the annual meeting of the Alumni Association of Rush College, held on the same day, Dr. William Fox, of Milwaukee, was elected president for the ensuing year. The Committee on Prize Essays reported that no essay had been received which in their judgment was worthy of either the first prize of $400 or the second of $50. They recommended, however, the essay entitled Inhibitory Forces for honorable mention. The Association voted to offer, instead of the two prizes heretofore offered, one of $500 for the best essay embodying original investigation, by an alumnus of the college; essays to be presented to the committee by or before February 1, 1886.

— The medical staff of the Charitable Eye and Ear

Infirmary have established a school of ophthalmology and otology for practitioners. Its courses of instruction will be four weeks in length, thus corresponding to the practitioners' courses at the colleges. The clinical facilities of the infirmary are unexcelled. More than a hundred out-patients come to the dispensary for treatment each day, and there are nearly a hundred resident patients. The fee for the course is twenty dollars.

Correspondence.

LETTER FROM BALTIMORE.

Baltimore, *February* 28, 1884.

Mr. Editor, — As some months have elapsed since a letter from Baltimore has appeared in the Journal, perhaps a brief account of the most important medical events which have occurred in that city during the interval will not be uninteresting to your readers.

The health of the city has, on the whole, been better than that of last year for the same time, and we have had no epidemics, unless a mild type of measles, which has been very prevalent here during the last three or four months, may be called epidemic. The secretary of our city Board of Health says it may not.

Our *four* medical schools (to which number a *fifth* has recently been added) began the session of 1883–1884 with about the usual number of students, and in a few weeks that goodly number of American physicians already dispensing good (or evil) will be increased by some three hundred or more "doctors of medicine."

The *fifth* school, to which reference has been made above, was chartered under the title of The Baltimore Polyclinic and Post-Graduate Medical School. Its *raison d'être* is the fact that the four medical schools previously in existence require for graduation attendance on but two sessions of lectures (of less than six months each in the University of Maryland and the College of Physicians and Surgeons, and less than nine months in the Baltimore Medical College and the College for Women), and none of these schools offer special facilities for post-graduate students. Indeed, the classes of under-graduates at the two schools which are connected with hospitals and large dispensaries are so full, and the time of the students so closely occupied by the didactic lectures, not to mention dissecting and parallel study, that individual clinical observation is well nigh impossible.

The incorporators of the Polyclinic do not intend to confer diplomas, but to supplement the instruction given by the other schools in order to attract to Baltimore some of that large number of physicians, notably from the South, who go for post-graduate advantages to New York or Philadelphia when not deterred by distance from going anywhere. The following are the professors and their departments: Alan P. Smith, surgery; J. Edwin Michael, genito-urinary surgery; B. B. Browne and T. A. Ashby, gynæcology and obstetrics; Samuel Theobald, diseases of the eye and ear; H. Clinton McSherry, diseases of the throat and chest; Robert B. Morison, dermatology and syphilis; Randolph Winslow and John W. Chambers, operative surgery; T. Barton Brune, practice of medicine; William A. Moale, orthopædic surgery; Thomas S. Latimer and Ferdinand E. Cleatard, diseases of children. Diseases of the nervous system and pathology are not yet represented, but are expected to be in a short time. Many of these gentlemen are connected with one or more of the other schools, so that the Polyclinic will not be considered by them "a rival in the field."

During November and the early part of December Dr. Billings delivered, in Hopkins Hall, a very interesting series of lectures on Municipal Hygiene. The lectures were given under the auspices of the Johns Hopkins University, and were intended for the students of the university, physicians, and the general public. In forming his statistics regarding the healthfulness of Baltimore and the expectation of life of its inhabitants, Dr. Billings took as a basis for calculation the United States, and not the city police, census. Of course, therefore, his conclusions are somewhat different from those of the city Board of Health, which latter, as you, Mr. Editor, remember, are based upon the police census, and re-enforced by certain curious and ingenious methods of enumeration. He states that the mean-after-life-time of a white male infant born in Baltimore is but little over thirty-six years, and of a colored male infant only twenty-one years.

In an amusing way he ridiculed the present ward boundaries, which he thought were entirely worthless (except, perhaps, from a political point of view), and showed that they would much impair the value of the ward sanitary statistics.

One of the subjects, to which he devoted nearly the whole of two lectures, and which is particularly interesting to Baltimoreans, was that of sewerage.

We have in Baltimore upwards of 60,000 cess-pools, and our soil is pretty well honeycombed and polluted by them. How to abolish these and establish a first-rate system of sewerage, without undue expense, is the most important sanitary question with which we, at present, have to deal. Dr. Billings, after mentioning the objects and principles of sewerage, spoke in a general way about some particular systems, especially those of Waring, Liernur, and Berlier. Of the latter he said it had but recently been introduced into Paris, and it was too soon to speak of its merits. He spoke approvingly of Colonel Waring's system, and mentioned the advantages which a separate has over a combined system. He also said it was the urgency of the occasion and the cheapness of the Waring system which had occasioned its adoption for Memphis. The Liernur plan he considered had some merits, but it "is a very costly one, both for construction and maintenance, . . . and it is condemned by the leading engineers of England, France, Germany, and America." His opinion has the more weight because it is in accordance with the views expressed by Colonel Waring and City Engineer Latrobe, at the State Sanitary Convention, held in this city the 21st and 23d of last November; and because it is directly opposed to the opinion of Dr. Chancellor, the secretary of our State Board of Health. The latter, some eighteen months ago went to Europe, to investigate sanitary matters, and came back very much impressed with the advantages of Captain Liernur's system of sewerage; so much so, that at the last annual meeting of the State Medical and Chirurgical Faculty he read a paper in which he warmly praised this system, and spoke of it as "destined to supersede all other systems now in vogue." In answer to the views of Dr. Billings and the other above-mentioned gentlemen he has published quite a lengthy article in the *Mary-*

land Medical Journal for December 15th last. This question of the best system of sewerage and the necessity for increasing the powers of the State Board of Health and establishing local boards throughout the State, as well as several other topics of less local interest, were considered at the Sanitary Convention mentioned above. This convention was composed of physicians prominent in the State, engineers, and others interested in sanitary matters. Its proceedings have been published in full in the Fifth Biennial Report of the State Board of Health; and, inasmuch as the practical outcome of the meeting has been the drafting of certain laws to be submitted to the Legislature now in session, it would be better to make them the subject of a future communication than to add an abstract of them to what, I am afraid, is an unduly long letter.

Before concluding, however, allow me to summarize briefly a striking report of ninety-nine lithotomies performed by Dr. Caleb Winslow of this city. This report has been published in full in the *Maryland Medical Journal* for the 23d of this month, but it seems to deserve an even more extended notice.

Of these operations ninety-eight were successful, one unsuccessful; in the latter case the patient, a negro, aged eighteen years, died from dysentery and peritonitis. Of those operated on ninety-eight were males, one a female; seven were adults, ninety-two children; the oldest was seventy years, the youngest three years; ninety-three were whites, six blacks. The number of stones removed was 109, three being the largest number removed from any one person. Stone recurred in but one case, in the patient aged seventy years, and it was successfully removed.

His method of operating was the left lateral. At times a bilateral incision was made to facilitate the removal of large stones. In the female case a stellar incision was made into the urethra, and this was dilated, a large stone being removed. The instruments used by him were curved staff, with gorget eight times, with scalpel ninety-one. Most of the stones were removed entire, a few had to be crushed. One measuring four and a half inches in its shortest, and five and a half in its longest, diameter was removed entire. The weight and dimensions of other calculi are not given.

The larger number of these operations were performed in eastern North Carolina and within a period of eighteen years, and before the development of Bigelow's operation.

Very respectfully, B.

A PLEA FOR CONSISTENCY.

MR. EDITOR, — Can you tell me why it is, now that so many of the great nations are adopting the weights and measures of republican France, that the world continues to be disgraced by a division of time so absurd as that which has come down to us from the dark ages of antiquity? Why should civilized humanity reckon twelve months to each year simply because a lot of Chaldees and Egyptians chose to reckon twelve arbitrary signs to their zodiac? Why split the day into twelve hours and each hour into five times twelve minutes and seconds merely because these same primitive star-gazers saw fit to carry out their whimsical subdivision to this extreme length? Why, finally, should a man worship God just one day out of seven because the ancients happened to be acquainted with only just that number of planets? Yet such is the system under which we all live and die to this hour.

They managed these things so much better in France, in the early days of the first republic, when the philosophers and emancipators had it all their own way, before the "*rois conjurés*" of Europe stepped in and delivered them up again to the tyranny of established usage!

You remember well, Mr. Editor, the history of the republican calendar, that brilliant effort of the human reason to free itself from the trammels of traditional superstition; its *decimal* Sunday, its scientific nomenclature, its commemoration of the heroes and philosophers of every age. Why did it die? Why do we not revive it and place it side by side with its twin sister the metric system as an example and model for future generations? Certainly they are both of a piece, and one is as philosophical and worthy to be adopted as the other. W.

Miscellany.

THE AMERICAN PRACTITIONER ON THE LOUISVILLE MEDICAL COLLEGE.

THE February issue of the *American Practitioner* contains an article by one of its editors, Dr. David W. Yandell, to which those who are interested in maintaining any professional or educational medical standard in this country are particularly referred. The practices there exposed, if truthfully reported, — and we see no reason to doubt it, — make, at this distance, very unpleasant reading, and in Louisville itself can hardly result otherwise than in degrading both the teachers and the students directly concerned in them.

INOCULATION OF TUBERCULOSIS.

AT a recent meeting of the Académie de Médecine, M. Verneuil related the following history: In July, 1877, a house surgeon (interne) at the St. Eugénie Hospital, who performed all the post-mortem examinations, one day noticed a papule at the base of the nail of his third finger. The apex presented a white spot, and a few drops of pus escaped from it. It was frequently cauterized, but the phalanges became attacked, and a cold abscess spread over the back of the hand. After three years' treatment, having failed to produce any improvement, M. Verneuil amputated the finger. The house surgeon was believed to be cured, and practiced in the provinces. Quite recently he has been again attacked by cold abscesses in the lumbar region, causing intense pain; during violent attacks of pain the arms exhibit clonic convulsive movements. M. Verneuil has operated a second time. He is convinced that his patient became inoculated with tuberculosis when performing a necropsy. A similar misfortune happened to Laënnec. One day, when operating on a tuberculous patient, he slightly cut himself with a saw. A swelling appeared on the wounded part. Laënnec cauterized it with antimony-chloride. The swelling disappeared, but twenty years subsequently he died from tuberculosis. — *Paris Corr. Brit. Med. Journal.*

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 23, 1884.

Deaths reported 2652 (no reports from Cincinnati and Buffalo): under five years of age, 1055: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 386, lung diseases 384, consumption 374, diphtheria and croup 145, scarlet fever 50, typhoid fever 47, measles 31, diarrhœal diseases 29, cerebro-spinal meningitis 25, malarial fevers 24, small-pox 20, whooping-cough 12, erysipelas 12, puerperal fever 11. From *measles*, Baltimore 12, New York six, District of Columbia five, New Orleans and Nashville three each, Chicago two. From *diarrhœal diseases*, New York 11, Chicago four, Brooklyn, Baltimore, St. Louis, and New Orleans three each, Lowell and Cambridge one each. From *cerebro-spinal meningitis*, New York five, Philadelphia, Lowell, and Worcester three each, Chicago and St. Louis two each, Boston, Charleston, Lynn, Holyoke, and Newton one each. From *malarial fevers*, New York 12, St. Louis four, Baltimore and New Orleans three each, Brooklyn two. From *small-pox*, New Orleans 17, Philadelphia, Nashville, and Holyoke one each. From *whooping-cough*, New York three, Boston two, Philadelphia, Brooklyn, Chicago, Baltimore, St. Louis, Pittsburg, and Chelsea one each. From *erysipelas*, New York, Chicago, New Orleans, and District of Columbia two each, Brooklyn, Boston, St. Louis, and New Haven one each. From *puerperal fever*, New York and Chicago three each, Philadelphia, Brooklyn, Boston, St. Louis, and Providence one each.

Three cases of small-pox were reported in St. Louis; diphtheria 20, scarlet fever 48, typhoid fever seven, and measles one in Boston; scarlet fever 14 and diphtheria four in Milwaukee.

In — cities and towns of Massachusetts, with an estimated population of 1,411,763 (estimated population of the State 1,955,104), the total death-rate for the week was 16.72 against 16.28 and 19.26 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,620,975, for the week ending February 2d, the death-rate was 20.5. Deaths reported 3448: acute diseases of the respiratory organs (London) 367, whooping-cough 126, scarlet fever 101, measles 75, fevers 38, diphtheria 36, diarrhœa 29, small-pox (Birmingham seven, Liverpool three, Sunderland two, London and Wolverhampton one each) 14. The death-rates ranged from 13.1 in Derby to 28.1 in Oldham; Leicester 14.9; Bradford 18.4; Liverpool 19.2; Blackburn 19.4; Sheffield 20.3; Nottingham 20.6; London 20.7; Manchester 23.9; Newcastle-on-Tyne 24.1; Leeds 24.9. In Edinburgh 22.8; Glasgow 23.6; Dublin 29.7.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending February 9th, the death-rate was 20.6. Deaths reported 3466: acute diseases of the respiratory organs (London) 347, whooping-cough 124, scarlet fever 94, measles 53, fever 44, diarrhœa 35, diphtheria 28, small-pox (Birmingham nine, London four, Liverpool and Sunderland three each, Wolverhampton and Manchester one each) 21. The death-rates ranged from 15.3 in Wolverhampton to 27.9 in Manchester; Blackburn 19.4; London 19.5; Birmingham 19.6; Nottingham 20.3; Leeds 21.4; Sheffield 22.1; Liverpool 23.3; Newcastle-on-Tyne 23.8; Leicester 24; Birkenhead 24.1. In Edinburgh 22.2; Glasgow 26.7; Dublin 30.

For the week ending February 9th, in the Swiss towns, there were 39 deaths from consumption, lung diseases 28, diphtheria and croup 12, diarrhœal diseases 10, whooping-cough three, measles one, small-pox (Winterthin one) one. The death-rates were at Geneva 18.3; Zurich 15.8; Basle 14.7; Berne 27.8.

For the week ending February 2d, in the Swiss towns, there were 32 deaths from lung diseases, consumption 20, diarrhœal diseases 16, whooping-cough seven, diphtheria and croup six, measles, scarlet fever, puerperal fever, and typhoid fever two each, small-pox one. The death-rates were, at Geneva 22.4; Zurich 13.8; Basle 18.6; Berne 24.4.

The meteorological record for the week ending February 23d, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OBITUARY.

DR. GEORGE ENGELMANN, the oldest practitioner in St. Louis, and the father of Dr. George J. Engelmann, died of pneumonia on February 4th, in the seventy-sixth year of his age. He was born in Frankfort-on-the-Main in 1809, and came to the United States in 1832, after having received his education at the Berlin, Heidelberg, and Würzburg Universities. He was one of the founders of the Western Academy of Science in 1836, and, later, one of the originators of the St. Louis Medical Society. In 1856 he was largely instrumental in founding the St. Louis Academy of Science, and was for many years president of that body. He had a high reputation as an authority in botany, and for forty-seven years he made it a part of his occupation to take meteorological observations several times a day, and only discontinued this practice two days before his death.

DR. JOHN HUTTON BALFOUR, Emeritus Professor of Medicine and Botany in the University of Edinburgh, Regius Keeper of the Royal Botanic Garden, and Queen's Botanist for Scotland, is dead at the same age, seventy-six. He was a member of many learned societies, both at home and abroad, and was the author of a variety of books and articles on botany, including the Manual of Botany and Botany and Religion.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM FEBRUARY 22, 1884, TO FEBRUARY 29, 1884.

BROWN, JOSEPH B., lieutenant-colonel, and BILLINGS, JOHN S., major, surgeons, directed to attend the International Health Exhibition in London, and, as delegates, the International Medical Congress at Copenhagen, to be held in May and August next, respectively; also to include Berlin in their route to or from Copenhagen, and to be governed by special instructions from the Surgeon-General in complying with this order. S. O. 44, paragraph 8, A. G. O., February 21, 1884.

WOODWARD, JOSEPH J., major and surgeon. Leave of absence still further extended six months on account of sickness. S. O. 44, paragraph 11, A. G. O., February 21, 1884.

HORTON, S. M., major and surgeon. Having reported at these headquarters, from leave of absence, ordered to Fort Hays, Kansas, for duty. S. O. 40, paragraph 2, headquarters, Department of Missouri, Fort Leavenworth, Kansas, February 20, 1884.

PATZKI, JULIUS H., captain and assistant surgeon. Leave of absence extended one year on surgeon's certificate of disability, with permission to go beyond sea. S. O. 43, paragraph 9, A. G. O., February 20, 1884.

MADDOX, T. J. C., first lieutenant and assistant surgeon. Assigned to temporary duty at Meyer's Springs, Texas. Per post orders, No. 27, paragraph 1, Fort Clark, Texas, February 13, 1884.

DIETZ, WILLIAM D., first lieutenant and assistant surgeon. Assigned to temporary duty at U. S. Military Academy, West Point, N. Y.

PHILLIPS, JOHN L., first lieutenant and assistant surgeon. Assigned to temporary duty in Department of the East.

MEAMS, EDGAR A., first lieutenant and assistant surgeon. Assigned to duty in Department of Arizona.

KNEEDLER, WILLIAM L., first lieutenant and assistant surgeon. Assigned to duty in Department of Dakota.

BLACK, CHARLES S., first lieutenant and assistant surgeon. Assigned to duty in Department of Texas.

S. O. 46, paragraph 1, A. G. O., February 25, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING MARCH 1, 1884.

WHITAKER, H. W., assistant surgeon, from the Portsmouth, and on sick leave.

GREEN, E. H., passed assistant surgeon, from Museum of Hygiene, and waiting orders.

DEATH. — Died, at Lawrence, Mass., February 10, 1884, Michael Roberts, M. D., M. M. S. S.

SUFFOLK DISTRICT MEDICAL SOCIETY. SPECIAL MEETING. — The *Section for Clinical Medicine, Pathology, and Hygiene* will meet at 19 Boylston Place, on Wednesday, March 12th, at 7.45 o'clock. The following papers will be presented: Dr. G. Liebmann, Spinal Irritation and Neurasthenia. Drs. S. G. Webber and J. J. Putnam will open the discussion. Dr. T. A. DeBlois, Tonsillitis. Drs. J. W. Farlow and Morton Prince will open the discussion.

ALBERT N. BLODGETT, M. D., *Secretary.*

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held at the Medical Library Rooms, on the second Thursday of March, at four o'clock P. M. Subject: The Discussion of the Best Methods of Wound Treatment. Dr. H. O. Marcy will open the discussion with a brief paper upon Aseptic Surgery. Dr. H. C. White will report a Case of Recto-Vaginal Fistula treated by a New Method. Profession invited.

HENRY M. FIELD, M. D., *Secretary.*

PROVIDENCE MEDICAL ASSOCIATION. ELECTION OF OFFICERS. — The annual meeting of the Providence Medical Association was held in the Medical Library, March 3, 1884, and the following officers elected for the ensuing year: President, Dr. W. J. Burge. Vice-President, Dr. E. T. Caswell. Secretary, Dr. Frank B. Fuller. Treasurer, Dr. Byron Whitford. Standing Committee, Drs. H. G. Miller, G. Radeke, G. D. Hersey, G. A. Pierce, G. W. Porter. Committee on the Reading Room, Drs. G. D. Hersey, H. G. Miller, G. W. Porter.

BOOKS AND PAMPHLETS RECEIVED. — Tribute to the late James Marion Sims, M. D., LL.D. By W. O. Baldwin, M. D., of Montgomery, Ala.

Cooper Medical College, San Francisco. Annual Announcement. Session of 1884.

MODERN LEGISLATION RELATIVE TO ADULTERATION OF FOOD AND DRUGS.

BY SAMUEL W. ABBOTT, M. D.,
Health Officer of Massachusetts Board of Health, Lunacy, and Charity.

HOWEVER appropriate the customary historical review of a subject may be in an elaborate treatise, I shall devote but a brief portion of this paper to the discussion of the ancient practices relating to food and drug adulteration. The usual history of petty crimes, traced back through centuries to the classic days of Greece and Rome, is repeated in the matter of adulteration. Pliny and Vitruvius and others tell us that opium was adulterated with the juice of other plants, and tests were prescribed for the detection of the fraud. Bread was adulterated with white earth obtained near Naples, and frauds in the making of wine were so common at Athens as to require the appointment of inspectors to prevent and expose the practice.

The disposition of many of the human race to cheat their neighbors has proved to be the mainspring of a continuous and an increasing industry from the earliest times up to the present. Just so long as avarice shall continue to be a ruling passion among men so long will legislation be needed to prevent adulteration, sophistication, and other forms of debasement.

The first English law on record relative to adulteration was enacted in the eleventh century, in the reign of Henry III. By the provisions of this law the pillory and the tumbril [1] were prescribed for the punishment of dishonest bakers, brewers, and others.

Dr. Blyth quotes the following quaint passage from an old paper entitled A Quip for an Upstart Courtier: —

"For you, goodman baker, you that love to be seen in the open market-place, upon the pillory, the world cries out on your wiliness. You buy your corne at the best hand, and yet will not be content to make your bread weight by many ounces. You put in yeaste and salt to make it heavie, and yet all your policie cannot make it. The poor crie out, the rich find fault, and the lord maior, and the sheriffs, like honourable and worshipful maiestrates, every daie walk abroad and weigh your bread and yet all will not serve to make you honest men. But, were extremities used and the Statutes put in the highest degree in practice, you would have as few eares on your head as the collyer."

An ordinance of 1316 prescribed that "no one shall mix any manner of wares, that is to say, shall put old things with new, or new things with old, by reason whereof the good thing may be impaired by the old, nor yet things of one price, or of one sort, with other things of another sort. . . . Also that no man shall moisten any manner of merchandise such as saffron, ginger, alum, cloves, and such manner of things as admit of being moistened."

During the following three centuries groceries and drugs were sold in the same shop, the two trades being combined until 1617, when the apothecaries formed a separate body, and have since remained a distinct trade or occupation.

In France similar laws were in force from early periods relative to bread, wine, and other articles of food. As long ago as 1396 an ordinance was in force in Paris forbidding the coloring of butter with herbs, flowers, or drugs.

The sophistication of drugs was forbidden, and apothecaries also were forbidden to use exhausted drugs under a heavy penalty. Adulterated articles were to be seized and burned in front of the house where they were found.

In Germany likewise for several centuries severe penalties have been inflicted for the sale of adulterated bread, wine, and drugs. For the former a similar penalty was inflicted to that employed in England. The offender was put in a basket at the end of a long pole and plunged in a muddy pool.

MODERN ENGLISH LEGISLATION.

A select parliamentary committee on the adulteration of food was appointed in 1855, and began its labors by a careful investigation of the whole subject, many persons being summoned before the committee who were supposed to possess special information as to the various forms of adulteration which were common at that time. Dr. Hassall, whose careful work had formed a fitting prelude to this inquiry, contributed much valuable information. On the report of the commission the first general Adulteration Act was drafted, and became a law in 1860. By this act it was provided "that every person who shall sell any article of food or drink, with which, to the knowledge of such person, any ingredient, or material injurious to the health of persons eating or drinking such article, has been mixed, and every person who shall sell as pure or unadulterated, any article of food or drink which is adulterated or not pure, shall, for every such offense, on summary conviction of the same, pay a penalty not exceeding £5. with costs." [2]

A second offense was punishable by publishing the offender's name, place of abode, and offense, in addition to the fine.

The analysts under this act were at first appointed by the secretary of state, and afterward by the local government board.

In 1872 the act was remodeled, and other provisions were substituted, especially relating to willful adulteration and criminal intent.

These acts were crude, and during the fourteen years of their operation much dissatisfaction was expressed at the want of standards of common articles of food, at the disagreement of analysts, and at the conflicting decisions of magistrates as to the exact meaning of the term *adulteration* and other legal technicalities.

A new committee was therefore appointed in 1874, witnesses were again examined, greater care being taken to summon merchants, manufacturers, milk dealers, and other persons specially interested in the operation of the act. This committee recommended certain important amendments, and summed up the inquiry by stating that the public was "cheated" rather than "poisoned."

As the result of this inquiry other statutes were enacted in 1875, 1878, and 1879, these constituting the acts now in force in England. As these acts are lengthy the chief points of interest need only be referred to at this time.

The first two sections repeal all previous legislation upon the subject, and define certain terms employed in

[1] Ducking-stool.

[2] Blyth. Foods, their Composition and Analysis, London, 1882.

the act. All offenses under the act are then specified. Ten sections provide for the appointment of analysts, and define their duties. Eight sections prescribe the modes of procedure against offenders. Section 29 provides for the expenses of executing the act. Sections 30 and 31 relate to the special inspection and analysis of tea. Sections 33 and 34 provide for the application of the law in Scotland and Ireland.

The amendment of 1879 provided in addition that it should not be alleged in defense that the purchaser, having bought only for analysis, was not prejudiced by the sale. Other amendments of minor importance were made in the same year.

As a result of these acts there were examined in England, in 1881 and 1882, 32,708 samples specified as follows:[1] —

Year	Milk.		Butter.		Groceries.		Drugs.		Wines, Spirits, and Beer.		Bread and Flour.		Waters.		Sundries.		Totals.	
	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.	No. Analyzed.	No. Adulterated.

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	32,708	5418

In France a new impetus has been given to the work of food inspection by the establishment in all the important cities of municipal laboratories and the appointment of inspectors, who, in accordance with the statutes, have power to punish offenders against the laws. Laboratories have been established in Paris, Lyons, Marseilles, Bordeaux, and other large cities. The officials appointed for each are a director, inspectors, and chemists.

Samples are obtained at the markets and shops by the inspectors, in which duty they are assisted by the commissaires de police. They go in pairs to such places as are indicated by dissatisfied purchasers, and, where it is practicable, make cursory examinations at the place of sale. If adulteration is detected two samples are taken, sealed, numbered, and certified by them and also by the tradesman. One is taken to the laboratory, and the other reserved in case of a dispute. Special notice is taken of the condition of the establishment or place of sale as to cleanliness, etc.

The public are invited by notification to take advantage of the statutes, and to request analyses as often as they shall choose to exercise the privilege. Qualitative analyses are made gratuitously, and quantitive analyses are paid for by a fee of five to thirty francs, according to the cost. Statements relative to qualitative analyses are confined to the terms *good*, *passable*, *bad* (not injurious), and *bad* (injurious).

Quantitative analyses must define the exact composition of the article in question.

The laboratory receives two classes of samples, those contributed by the public and those received from the inspectors, while many samples are also analyzed which are obtained from the hospitals, prisons, and other public institutions. From the results of the laboratory work reports are sent to the public prosecutor, who institutes proceedings against offenders.

Much care is given to the work of ascertaining the normal composition of the different articles of food.

The laboratory is amply provided, and has a special photographic department for the purpose of showing clearly to a judge or a jury the palpable proof of adulteration, as in the case of spices, cereals, trichinæ, and other objects requiring ocular demonstration.[2]

The following table[3] shows the work of the laboratory for 1881: —

Total number of samples examined	6517
Percentage of adulteration, total of all samples	50.43
Percentage of adulteration, milk	50.67
Percentage of adulteration, wine	59.17

The samples were also classified as follows: —

Good	1565
Passable	1523
Bad (not injurious)	2608
Bad (injurious)	562
	6258

The remainder (259) were in process of examination at the time of the report.

The samples included, besides wines and milk, spirits, syrups, waters, butter, bread, chocolate, preserves, coffees, confectionery, spices, toys, and various other articles.

The German statutes regulating the sale of food and of drugs are at present not like our own, combined in one statute, but are entirely distinct. The principal law relating to the supervision of the sale of drugs bearing date March, 1872, and the latter, the food law, being enacted May 25, 1879. The drug law of 1872 regulates the sale of medicines, and establishes the German Pharmacopœia as the standard in place of those in use before the union and consolidation of the Empire. The food law regulates the sale of food and drink, dyes, carpets, toys, cooking utensils, and petroleum. Careful attention has been bestowed upon the subject in Germany. In 1878 231,478 samples of different articles were analyzed, and upon the evidence of these analyses 3352 convictions were obtained.

Switzerland also has stringent laws for the prevention of adulteration, especially in the Canton of Zurich.

[2] Analyst, vol. vii.
[3] Documents sur les Falsifications des Matieres Alimentaires. Paris. 1882.

Canada has made commendable progress in the same direction, as shown by the reports issued annually since 1876 by the Inland Revenue Department. A summary of the work there accomplished for the six years beginning in 1876 is as follows:[1] —

No. of Analyses.	Genuine.	Adulterated.	Doubtful.	Total.	Per Cent. Adulterated.
1876	87	93	—	180	51.66
1877	241	247	—	488	50.61
1878	523	271	19	813	33.33
1879	619	235	42	896	26.22
1880	728	295	20	1043	28.28
1881	749	260	38	1041	24.97

UNITED STATES.

The thorough investigations of the Parliamentary Committee, and the subsequent legislation in England, were soon followed by similar inquiry in the United States.

Special work had already been accomplished by State Boards of Health, notably those of Massachusetts and Michigan, in the examination of food, during the past ten or fifteen years.

It needs but a passing reference that volumes of sensational and exaggerated statements have been written upon this subject. Column after column of wild assertions as to special articles of food have appeared in the public prints, until the timid consumer is almost driven to starvation as a last resort.

The first movement in the United States toward general legislation for the prevention of this existing evil was initiated by the National Board of Trade in 1879.

DRUG INSPECTION.

It should be said, however, in relation to the department of drug inspection, that valuable work had already been accomplished by the formation of the American Pharmaceutical Association, which for many years exerted a powerful influence in the direction of a pure supply of drugs.

A law had already been enacted by Congress in 1848, providing for special examiners of drugs at important sea-ports. At one port alone (New York) the examiner rejected in nine years 900,000 pounds of adulterated drugs. Political influence interfered very much with the efficiency of this law, and at some ports rendered it inoperative. The amount of adulteration of drugs previous to the enactment of the law referred to was very great. On the authority of Dr. Bailey, the United States drug inspector for the port of New York from 1848 to 1857, nearly one half of the drugs imported were adulterated. Establishments existed in England, Germany, Belgium, and France, where drugs were "prepared with special reference to their sale in the United States." The existence of establishments in this country where adulterations have been systematically practiced has also been demonstrated, especially with reference to powdered drugs.[2]

Reasons for the existence of such practice are by no means wanting. Many dealers enter upon their business with the sole idea of profit. Competition naturally follows until profit is no longer possible. As a further consequence adulteration and the sale of inferior substitutions follow. The manufacturer is sought who sells at the lowest price without regard to quality.

The actual effect of such practice on the health of the people is plainly stated in a recent report to the National Board of Health by Prof. C. L. Diehl, of Louisville, Ky., who says: "One need not be a physician to appreciate the fact that satisfactory medication is impossible when the medicine administered is not that designed by the prescriber. It is not sufficient that the medicine should be '*very nearly*' that which is designed; it should '*absolutely*' correspond to the standard, which the physician has before his mind at the time when he finds it necessary to prescribe it. It is therefore the duty of the dispenser to see to it that the medicines he dispenses conform in every respect to the standard that has been framed for his guidance as well as for the guidance of the physician. The fulfillment of these conditions depends not alone on the integrity of the dispenser, it depends equally on his knowledge and skill; and unless these are combined with integrity the prescriber cannot hope for results which the nature of the disease may justify him to expect. Finding that the medicine has not the expected effect, the prescriber may be led to increase the dose or to replace that originally prescribed by another, without, however, ameliorating the disease or causing it to yield to his treatment. He now perchance begins to suspect that the medicine supplied is not as it should be, and changing his apothecary, soon cures his patient.

"If all cases of bad medication were as simple in their development as the one illustrated there would perhaps be no necessity for this report. Unfortunately, however, such is not the case. It quite often happens that, the diagnosis being well established, it is urgent that the proper medicine should be properly administered. If in a case of this nature the medicine should happen to be of indifferent or inferior quality the life of the patient is placed in jeopardy, and under some circumstances sacrificed. Again, the prescriber, conforming the medication to his diagnosis, may be led to reject that originally made, because he fails to obtain the effect which an abundant experience justifies him to expect from the drug administered. In a case of this kind he may for a time be completely at fault, while the illness of his patient is vexatiously prolonged, or, it may be, aggravated. In short, the use of inferior and adulterated medicines may be the cause of protracted disease, of increased suffering, and in some instances of death; and failing to mitigate and cure diseases in which pure medicine is unequivocally indicated they may lead the physician to errors in diagnosis, cause him to acquire the habit of prescribing large doses of active medicines, and, in fact, seriously affect his success and reputation."

Let me not be understood in this connection as considering drugs to be the *sine qua non* of therapeutics. The physician who uses them to the exclusion of such important remedial measures as heat and cold, light, fresh air, electricity, massage, diet, etc., has hardly learned the alphabet of practice. But if we must use drugs at all, and especially such important remedies as

opium, and quinine, and ether, and alcohol, let us be assured that they are of a definite strength, and when the physician prescribes a gramme of quinine or twenty-five drops of laudanum let him know that the pills for which he writes, on the one hand, contain just the amount of the alkaloid prescribed, and that the laudanum also has been made from opium of a standard strength, and not from a cheap or exhausted article.

Special laws relating to certain articles of food and drink have existed in this State for many years. Fish, meat, milk, cocoa, vinegar, butter, and cheese have all been the objects of legislation, and provision has been made for their inspection by local officers. But in later years the need of a general, comprehensive law, which should include everything used as food, or drink, or medicine under one statute, has been urged as a necessity both of national and of State legislation.

The inquiry of the National Board of Trade, inaugurated in 1879, resulted in the recommendation of a law, which, with but few modifications, has been adopted in the States of New York, Michigan, Massachusetts, and New Jersey. This law was enacted in our own State in May, 1882, and took effect in the following August. The law as then enacted is as follows: —

[CHAP. 263.]

An Act relating to the Adulteration of Food and Drugs.

Be it enacted, etc., as follows:

SECT. 1. No person shall, within this Commonwealth, manufacture for sale, offer for sale or sell any drug or article of food which is adulterated within the meaning of this act.

SECT. 2. The term "drug" as used in this act shall include all medicines for internal or external use, antiseptics, disinfectants and cosmetics. The term "food" as used herein shall include all articles used for food or drink by man.

SECT. 3. An article shall be deemed to be adulterated within the meaning of this act, —

(*a.*) In the case of drugs, — (1.) If, when sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality or purity laid down therein; (2.) If, when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia, or other standard work on *materia medica*, it differs materially from the standard of strength, quality or purity laid down in such work; (3.) If its strength or purity falls below the professed standard under which it is sold:

(*b.*) In the case of food, — (1.) If any substance or substances have been mixed with it so as to reduce, or lower, or injuriously affect its quality or strength; (2.) If any inferior or cheaper substance or substances have been substituted wholly or in part for it; (3.) If any valuable constituent has been wholly or in part abstracted from it; (4.) If it is an imitation of, or is sold under the name of, another article; (5.) If it consists wholly or in part of a diseased, decomposed, putrid or rotten animal or vegetable substance, whether manufactured or not; or, in the case of milk, if it is the produce of a diseased animal; (6.) If it is colored, coated, polished or powdered, whereby damage is concealed, or if it is made to appear better or of greater value than it really is; (7.) If it contains any added poisonous ingredient, or any ingredient which may render it injurious to the health of a person consuming it.

The State Board of Health, Lunacy, and Charity may from time to time declare certain articles or preparations to be exempt from the provisions of this act; and the provisions hereof shall not apply to mixtures or compounds recognized as ordinary articles of food, provided that the same are not injurious to health, and are distinctly labeled as mixtures or compounds.

SECT. 4. The State Board of Health, Lunacy, and Charity shall prepare and publish from time to time lists of the articles, mixtures or compounds declared to be exempt from the provisions of this act, in accordance with the preceding section. The said board shall also from time to time fix the limits of variability permissible in any article of food, or any drug, or compound, the standard of which is not established by any national pharmacopœia.

SECT. 5. The State Board of Health, Lunacy, and Charity shall take cognizance of the interests of the public health relating to the sale of drugs and food and the adulteration of the same, and shall make all necessary investigations and inquiries in reference thereto, and for these purposes may appoint inspectors, analysts and chemists, who shall be subject to its supervision and removal.

Within thirty days after the passage of this act the said board shall adopt such measures as it may deem necessary to facilitate the enforcement hereof, and shall prepare rules and regulations with regard to the proper methods of collecting and examining drugs and articles of food. Said board may expend annually an amount not exceeding three thousand dollars for the purpose of carrying out the provisions of this act.

SECT. 6. Every person offering or exposing for sale, or delivering to a purchaser, any drug or article of food included in the provisions of this act, shall furnish to any analyst or other officer or agent appointed hereunder, who shall apply to him for the purpose and shall tender him the value of the same, a sample sufficient for the purpose of the analysis of any such drug or article of food which is in his possession.

SECT. 7. Whoever hinders, obstructs, or in any way interferes with any inspector, analyst, or other officer, appointed hereunder in the performance of his duty, and whoever violates any of the provisions of this act, shall be punished by a fine not exceeding fifty dollars, for the first offense, and not exceeding one hundred dollars for each subsequent offense.

SECT. 8. This act shall take effect at the expiration of ninety days after its passage. (Approved May 26, 1882.)

This law has certain points in common with that now in force in England, and also some notable points of difference.

Each law distinctly defines certain terms which are used therein. This feature of the law has the obvious advantage of saving an endless discussion in the courts upon the meaning of terms in the statute. The words *drug* and *food* are clearly defined in each law, and in the Massachusetts law (or rather the United States) the definition of *adulteration* is also stated with unusual clearness and precision.

In the case of drugs, the terms *differ* and *differ materially* are employed, the former relating to officinal preparations of the United States Pharmacopœia and the latter to others not officinal. The former is plainly a more stringent provision than the latter, and justly so, since the officinal preparations are the most commonly used and are by far the most important. Useful preparations when discovered, or proposed, are usually admitted to the Pharmacopœia at each decennial revision of the work. It would seem that a manual compiled with and by the consent of a commission of representative physicians and druggists from the entire country should be admitted as undoubted authority.

In the case of food the various modes of adulteration or debasement are carefully stated. Either one or several of these may exist in a given sample or article, as in the case of milk, in which either the first, third, fourth, fifth, sixth, seventh, or all of them may exist at the same time.

Certain exceptions are made in the British law: —

(1.) In the case of ingredients not injurious to health, *added* to render an article fit for carriage or preservation, and not to fraudulently increase its bulk, weight, or measure, or to conceal its inferior quality.

(2.) In case of patent medicines.

(3.) Where a drug is unavoidably mixed with some extraneous matter in the process of preparation or of collection.

Another clause provides that compound foods or drugs must be in accordance with the demands of the purchaser, with reference to the ingredients contained.

A legible descriptive notice or label attached to an article, stating that it is mixed, exonerates the seller.

The British law also provides that a buyer who purchases with intent to submit an article for analysis must notify the seller of such intention, and offer to divide the article into three parts, each part to be

sealed, and one part delivered to the seller, one part he retains, and the third is submitted to the analyst. If the seller does not accept the offer of the buyer to divide the article, the analyst on receiving it divides it into two parts, one of which he delivers to the purchaser to be reserved by him in case of prosecution.

The French Code also provides for a division of each article purchased into two portions.

In addition to the general law passed by the Legislature of Massachusetts in 1882 an amendment was enacted in the following year providing that the State Board should make prosecutions of offenders, and that a definite portion (two fifths) of the appropriation should be expended in the enforcement of the laws for preventing milk adulteration.

With these two laws upon the statute books we may now inquire what has been accomplished towards an improvement of the food and drug supply in Massachusetts, though such an inquiry may be deemed somewhat premature since less than eight months have elapsed since the enactment of the amendment of the statute.

In compliance with the law, two analysts were appointed soon after the date at which it took effect, and after the passage of the amendment the number of analysts was increased to four, two of whom were appointed for the sole purpose of milk analysis.

The period between the passage of the law of 1882 and the amendment of 1883 was chiefly occupied in the inspection and analysis of samples with reference to ascertaining the actual condition of the supply of the State. Samples have been collected in all parts of the State, chiefly in the cities and large towns.

The whole number analyzed has been about 1400. This number includes over 300 samples of milk.

The percentage of adulteration among drugs has been found to be forty per cent.

Among articles of food forty-seven per cent. were found adulterated within the meaning of the statute.

Of milk seventy-eight per cent. were found adulterated within the meaning of the statute.

Seventeen prosecutions have been entered in the courts on complaint of the Board, one of which was withdrawn in consequence of the death of the defendant. In all the other cases adulteration was satisfactorily proved, but in two of them the defendant escaped conviction in consequence of minor technicalities, while the remaining fourteen were convicted.

As a salutary result of the work thus far accomplished druggists have been stimulated to use greater care in the selection, the purchase, and the manufacture of pharmaceutical preparations. Grocers have appealed to their manufacturers to furnish a better and a purer supply, and milkmen have been taught a useful lesson. We do not pretend to say that Boston has yet a pure milk supply, but we do know that in many cases where we have made repeated analyses from the same establishments there has been a marked improvement.

Within the past six months, or since the prosecutions made by the Board, assayed drugs of definite known strength have become a recognized department of trade. Manufacturers doing business outside of the State have sent to their agents in Massachusetts requesting the return of all preparations which did not conform to the pharmacopœial standard. Wholesale dealers have employed chemists to examine their goods in order to insure a pure stock, and one which should conform as far as possible to recognized standards.

We venture the assertion that the amount of chemical analysis and assay has been far greater in Massachusetts during the past year than ever before, without reference to the official work of the Board.

Certain objections, amendments, and substitutes have been presented to the Act of 1882. These may be enumerated as

(1.) Local Inspection. While, on the one hand, this mode of operation may have certain theoretical advantages, such as a distribution of the work of supervision and a greater convenience to sparsely-settled districts, on the other hand the practical operation of local inspection in Massachusetts has been a failure for many years past. The reasons may be stated briefly: the petty influence of local politics, frequent changes in office, inadequate compensation, and incompetency. Nothing illustrates this better than the habitual use of the lactometer by milk inspectors to the exclusion of thorough chemical analysis. The fallacy of this instrument is so well known that further reference to it is unnecessary.

(2.) Proof of criminal intent on the part of the seller. The insertion of this provision in the present law is all that is desired by the men who sell water in place of milk, or gypsum for cream of tartar, or inferior grades of drugs for those of standard strength. Such a provision would render the law practically inoperative.

(3.) The insertion of a limiting word like "essentially" or "materially" after the word "differs" in the first clause relating to drugs. By this amendment a loose construction of the law and a sliding scale would result; drugs could be sold of a quality corresponding to the price paid, and standards would be ignored. The prescriber might find the one-grain, or two- or five-grain quinine pills containing three fourths or one half these quantities. In some of the preparations examined by the analysts of the Board the strength has been found to be less than one third of that required by the statute.

No better amendment has been proposed to the present law than such as shall provide for its more thorough and rigorous enforcement, such, in fact, as shall protect the honest manufacturers and producers, and at the same time give to the people, the consumers, everywhere and at all times, the opportunity to test for themselves, for a reasonable fee, the quality of the goods which they use. Such a result might be secured in Massachusetts by the establishment of a State laboratory, such as has recently been organized in Paris for the same purpose. At such an institution, properly equipped with chemical apparatus for analysis, with microscopes for food and drug examination, with apparatus for photography, and all other departments requisite for food and drug inspection, all the work now done by the analysts could be performed; and, also, any individual desiring a certificate of analysis of an article could have the work done at the mere cost thereof. The number of persons presenting material for analysis is by no means small. Scarcely a day passes in which some one does not bring to the office of the Board a sample of food or of drugs for this purpose. These people represent the consumers and the retailers who cannot know with certainty the character of the goods which they purchase.

A public laboratory might also be used for the anal-

ysis of all the public water supplies of the State, both for the chemical and for the biological work which they might demand, and also for the inspection of the food and drug supplies of all its hospitals, prisons, almshouses, and other public institutions.

GENERAL PARALYSIS OF THE INSANE.[1]

BY GEORGE F. JELLY, M. D.

CASE IV. S. S., aged forty, married, admitted November 12, 1870, native of Duxbury, Mass. Grandfather and grandmother insane. Said to have had a sunstroke eighteen years before admission to hospital. Habits said to be good. One year since, after hard work and unusual anxiety, he was dull, sluggish, and inactive; would rise in night and wander about in a bewildered manner. In many things seemed changed. Was indifferent to family. Several attacks of partial insensibility. Frequently tripped in walking. Became unable to attend to business, and was finally excited and bombastic. When first seen at asylum was feeble, dull, and bewildered, and he seemed like a rapid case, but he soon rallied, and became much more active mentally, though extravagant and tremulous in speech. He never had convulsions, and only slight semi-conscious attacks.

After two months he passed into a very comfortable state; he was quiet, his speech and gait scarcely affected, and to his friends he seemed almost well. In four months from his admission he left the asylum. He remained quite comfortable for a long time, but mentally weak. After a few months I lost sight of him, but have no doubt that he died some years since.

CASE V. E. A. L., aged forty-eight, married, cooper, a stout, vigorous, coarse, profane man, who has used tobacco and whiskey to excess. Has worked very hard, and has had much trouble with his wife. Six weeks before admission became irritable in manner, very unreasonable, and neglected his business to make foolish bargains; developed delusions of great wealth, but no tremor of lips and no unsteadiness in walking. Very indignant because brought to the asylum, but soon settled down, and declared he would not leave. Very extravagant, declaring he had bought the Fitchburg railroad, and would build a city at his home next summer which would be a "ripper." He failed quite rapidly, but never had convulsions. After some months he developed the usual paralytic symptoms in speech and walk. Ten months after admission he was transferred to Worcester, and died within two years from the inception of the disease.

The next case, No. 6, differs from those already described on account of the sudden and early death of the patient.

CASE VI. D. P. S., aged thirty-nine, single. Admitted February 16, 1872. Coal salesman; native of New York. Father "monomaniac" on subject of religion. His friends said that he had no excesses, but his subsequent history proved that he was somewhat addicted to wine and women. Had worked very hard, and had been subject to severe mental annoyance. He was a little excited one year since, after which he was somewhat melancholy. Within a few weeks had been extravagant, and inclined to make foolish bargains. On admission to asylum very voluble, somewhat incoherent, very happy and extravagant, and had a decided trip in speech. His talk was as follows: "Sheather, in New York is an old friend of mine. My friend Sheather is worth thirty millions. Ed is worth thirty millions, carried on by importing furs. He lives on Fifth Avenue. I have one hundred and fifty millions under my own control. I am the gayest boy out." Soon became entirely contented. Was continually making money; said he could make more money in the asylum than out in the world. He became more quiet, grew stout, but never gave up any of his extravagant ideas or lost the paralysis of speech or in his walk. Each meal was a feast fit for a king, and his room a palace. Seven months after admission he had his first epileptic convulsion, which was repeated several times during the first day, and for a time he was unable to swallow. For a week he had one or more fits every day, and then rallied, and was somewhat clearer. November 24th, nine months after admission, he was again seized with convulsions, but after three hours seemed pretty well. At nine P. M. he retired, and at ten he was dead.

The autopsy showed no gross changes in brain, except excessive congestion. Other organs normal.

CASE VII. J. W. C., aged forty-eight, married, retired sea captain. Admitted June 27, 1873. Said to have had a sunstroke six years before, and had always been a coarse, licentious man, addicted to excessive use of liquor. His friends say that he has been wrong mentally for two years. For thirteen months before admission to asylum had been a patient at Worcester Lunatic Hospital. Was very violent and homicidal at first. He was taken from Worcester on a writ of habeas corpus, attacked Dr. Fisher in court, was remanded to the hospital, and remained till his admission to the McLean. When he entered the latter institution he was mixed, confused, thick in speech, unsteady in gait, and extravagant, but pretty quiet.

He soon became very restless, and three months after admission had violent epileptic seizures, the convulsions being chiefly confined to left arm and leg, though there was marked twitching of both arms and legs. Following these attacks he never recovered his coherence, his left arm and leg became paralyzed and helpless, and he gradually failed. He became filthy, and with his right hand was very destructive. In this condition he was placed under the care of Dr. Mead, and in a few weeks died. An autopsy was made by Dr. Fisher (of which I have no copy).

By a singular coincidence the wife of this patient developed the most characteristic symptoms of general paralysis. I saw her but once, but the extravagance, tremor, and peculiarity of gait were all present. She was sent to the asylum at Concord, N. H., and Dr. Bancroft afterwards told me that hers was a typical case. She survived her husband less than a year.

CASE VIII. E. B. O., aged fifty-three, married, lawyer. Admitted May 23, 1875. One brother had been insane. He had lived very freely, using a good deal of wine, and had had great business anxiety. His was an entirely characteristic case, with more than usual incoherence and confusion. Paralytic symptoms very marked. He improved and left the asylum in six months, still quite weak, but comparatively clear mentally. He is living, his difficulty in articulation is quite marked, and his gait unsteady. He is always cheerful and exhilarated, but is able to live

[1] Concluded from page 225.

most of the time outside of an insane hospital, though sometimes placing himself under restraint voluntarily. He reads a good deal, and is able to make himself useful about his home. He resembles an overgrown child. He has had several apoplectiform seizures. It is more than eight years since the commencement of his disease. I think that there can be no mistake in the diagnosis as it has been confirmed by several physicians familiar with general paralysis.

Case IX. C. D. W., aged thirty-seven, married, architect. Admitted September 16, 1877. Had been subject to chronic diarrhœa. Had worked very hard, and has been made very anxious in settling an estate. For two months has seemed changed and strange. Developed extravagant delusions three weeks before entrance to the asylum, and for three days had been much excited. On admission his speech was thick, his lips tremulous, and he was very extravagant. He offered me at once a million dollars for the asylum. He soon became more excited, and had a long run of maniacal excitement, in which he was violent and homicidal. He was full of the most extravagant delusions, owned all the money and diamonds in the world, all the railroads could go round the world in two minutes, he could raise the dead, banish death, etc. After a few months became more quiet, but still deluded and threatening. He was taken through persistency of friends to Probate Court, where he manifested great excitement, but by advice of judge went away on a trip to California. Returned much more excited and much worse. After a time was more quiet; but gradually grew more dull and feeble, and died February 4, 1879, nineteen months after inception of disease, of exhaustion and lung symptoms.

Autopsy by Dr. E. G. Cutler: —

Rigor mortis well marked, body in good condition; not emaciated.

Nothing special about calvaria except that it was somewhat dense.

Vessels of dura mater full of blood. Membrane itself of normal thickness. Considerable increase of subarachnoid fluid. Pia mater much thickened, especially over apex; more marked over left convolutions than over right; at base of brain considerably adherent. Thickening at base less marked than at apex. Vessels at base showed no change.

Convolutions of brain, especially at vertex and in frontal region, decidedly atrophied, and on the left side at Isle of Reil quite a cavity had formed in marked contrast to condition of the brain on the corresponding portion of right side, which, however, was quite atrophied.

Pia mater quite firmly adherent to surface of brain, especially at vertex, producing slight lacerations of brain substance when removed.

Brain firm on section.

Amount of blood in brain not excessive.

Nothing abnormal in corpus callosum, pons, or medulla. No increase of blood or fluid in lateral ventricles.

Nothing abnormal in lateral sinuses.

Diaphragm on right side at fifth rib; on left side at fifth intercostal space.

Lower lobe of left lung adherent anteriorly over a limited space. Right lung adherent universally (old and dense adhesions). Some consolidation of lower lobe of left lung, and œdema of both lobes.

Red hepatization of a portion of lower lobe of right lung and considerable œdema.

Right side of heart distended by fluid black blood. Mitral valve admits two and one half fingers. Nothing remarkable about heart.

Spleen of normal size and color. On section dark and full of blood.

Left kidney normal in size. On section rather cyanotic. Capsule strips easily, leaving a smooth surface. Cortical portion healthy. Right kidney healthy. Nothing abnormal in intestines, liver, stomach, or bladder.

Case X. G. G. K., admitted December 10, 1870, aged forty-six, married, agent for express company. Uncle died insane.

A very active, healthy man, and an athlete. Very licentious, and has drank freely. One year before admission was dull and indifferent, irritable and suspicious. Soon afterwards he became excitable and pugnacious. Within three days talked very extravagantly, thinks himself irresistible to women. Two days after he entered the asylum, very happy and contented, and said that $10,000 would not tempt him to leave, and was full of suggestions of wonderful improvements in the institution. He said that he would deliver a lecture in Music Hall, and would issue one million tickets at $100 each.

Six weeks after admission very noisy and extravagant, violent and filthy. He frequently said, "I am God Almighty; I can do everything." In three months he was more quiet. In six months bland, effeminate, quiet, and demented. In fifteen months he was much troubled with hallucinations of hearing, his dementia was far advanced, and he was constantly muttering incoherently to himself. He was losing strength, but at that time manifested no paralysis whatever, and though this symptom was constantly looked for it never appeared, causing some doubt as to the diagnosis. In twenty months he was transferred to the Worcester Hospital, where he died about four years after the inception of the disease, or from his first exhibition of mental symptoms. The superintendent sent me this copy of the autopsy: —

Right pupil dilated to twice the size of left. Scalp torn off with great difficulty. Skull dense and of normal thickness. Dura mater abnormally adherent to calvaria, cloudy, and greatly thickened. On removal of skull-cap the brain appeared in color like healthy pus, especially over the openings into the convolutions. Subarachnoid spaces contained serum, normal in amount. Pia mater of the thickness of vellum writing paper, peeling off without difficulty from the substance of the brain. Convolutions not deep or numerous. Brain substance more than ordinarily firm. Corpus callosum, fornix, velum interpositum, and corpora quadrigemina healthy. Corpora striata and thalami symmetrical and normal in consistence and color, both on their surface and in their substance. Amount of fluid in the ventricles normal. Pons varolii, medulla oblongata, and cerebellum healthy. Cerebral arteries full of blood and their coats healthy.

Microscopical examination of the membranes of the brain shows great increase of fibrous tissue, infiltrated with an abundance of young cells. No appearance of fatty degeneration or other change in the brain substance itself.

Kidneys enlarged, their capsules easily torn off; vessels enlarged and injected. Extravasations frequent. Cells cloudy and granular. Connective tissue slightly increased. Other organs healthy.

CASE XI. Mrs. S. J., aged thirty-five, married, native of Massachusetts, was admitted to McLean Asylum in a state of great physical prostration, mental depression, and hypochondria, with a history of long-continued ill health. For weeks there were no indications of general paralysis. She manifested great mental distress, believed that she had been very wicked, thought that she must soon die, and that she could never see her husband again on account of her unworthiness. As she gained in physical strength she became somewhat exhilarated, at times very talkative, at other times emotional and tearful.

This state continued till nine months after she came to the asylum, when she seemed much confused, and became very extravagant in her ideas, believing herself some great and important personage. She then for the first time manifested tremor of lips and tongue and difficulty in articulation. Her conversation was as follows: —

"I would give all the world to tell you who I am. I cannot tell you who I am. I have but one husband, and he who is my husband writes his name through my head, my heart, my toes. It is God. I am a goddess. There is no more death. I don't wish to go into the yard with attendants. I am above them. I cannot associate with them. My associates are queens. God claims me." She would go on in this way for hours, accompanying her words with gestures, and articulating with difficulty.

During the next month she became more silly, entirely chaotic, and very untidy, and was much given to masturbation. She sat by herself giggling and smirking, and staggered very badly when she attempted to walk, swaying to either side, and using her hands to keep her equilibrium.

This state of things continued for five months, when she again seemed depressed, refused food, and was fed for some time with the stomach tube.

During the next four months she failed steadily, the paralytic symptoms increased, and she died in two years and nine months from the first appearance of mental symptoms. There were never convulsions, but several apoplectic seizures.

An autopsy by Dr. Fitz showed marked atrophy of brain, especially of middle lobe, with a few small cysts of the arachnoid.

PROTRACTED LETHARGY AFTER THE USE OF BROMIDE OF SODIUM BY ONE HAVING THE MORPHIA HABIT.[1]

BY E. G. CUTLER, M. D.

ON the 29th of April, 1880, I was called to see a man, said to be a morphia taker, who in trying to break himself of the habit had followed out sombody's "cure" for several days, and in consequence lay in a stupor.

The following history was obtained: —

The patient, a physician, had taken morphia subcutaneously for perhaps twenty years. Several times he got down to very small doses, and twice had left it off altogether for months. He had served in the army as a surgeon, and been honorably discharged several years before. Recently he had been an inmate of Dr. Day's Washingtonian Home, but all the time while there took opium surreptitiously, obtaining it without any difficulty, he said, from the engineer of the establishment. (In justice to Dr. Day it should be said that this employee is said to have been soon discovered and promptly discharged.)

On the 19th of April Dr. ——, my patient, commenced to follow out the cure laid down by Dr. Mattison in the *Quarterly Journal of Inebriety*, June, 1879. He took *sixty* grains of the bromide of sodium three times for the first twenty-four hours, and each day for the next seven days he increased the dose by ten grains over the dose of the preceding day, thus making an increase of thirty grains every twenty-four hours. When he had taken the dose one hundred and twenty grains thrice the cure was to be complete. This programme was carefully followed out for a whole week. On the first day he diminished the quantity of morphia he had been taking by one quarter (I think). The next day he did the same. The third and fourth days he rapidly diminished the morphia to a very small fraction, and on the fifth he omitted it entirely. To return to the history of the bromide. He got along well enough till the fifth day, feeling no special inconvenience, retaining his appetite and digestion, sleeping well, and attending to the calls of nature. On the fifth day he began to be somnolent, and prepared his doses of bromide for that and the next two days, and gave directions to be roused at the proper times to take his medicine and food in case he should be asleep, and requested his attendants to give him small doses of nitre daily. On this day he first kept his bed for the greater part of the time. The sixth day it was quite difficult to rouse him sufficiently to take his drugs and feed him; and on the seventh this difficulty had very greatly increased so that it was nearly impossible to give the last dose of the bromide. The act of swallowing was very slow.

From this time, the 25th of April, till I saw him on the afternoon of the 29th, his sopor progressively increased to lethargy, he had taken no food or drink of any kind into the stomach, but very little urine had been passed, and there had been no movement of the bowels. I found him in bed lying in a natural position, inclined towards the left, with a sunken countenance and a dusky earthy color of the skin. The pulse was very feeble and quite slow and the surface of the body cool. The temperature, though taken at the time, I unfortunately do not remember exactly; it was a little below the normal standard. The respiration was slow, rather superficial, and accompanied by no adventitious sound. The pupils were neither contracted nor dilated, and did not respond to the stimulus of light. There was no unpleasant odor to the breath, the mouth and lips were dry. The tongue could not be seen. Reflex motion could not be excited either by touching the conjunctiva, thrusting a feather up the nose, pinching, or otherwise irritating the skin. He could not be roused to consciousness, or to make any, even the slightest, movement. About four ounces of highly concentrated urine free from albumen were drawn by the catheter. Nothing had been swallowed for four days, though repeated attempts had been made to feed him. As his vitality seemed to be pretty low, enemata of milk, beef tea, and alcoholic stimulants were given at first, and at night small doses of strychnia were carefully tried, alternating with nitre.

The following day he looked less sunken and had a shade better color, the breath had the faintest trace of the unpleasant odor usually observed after large doses

[1] Read before the Boston Society for Medical Observation, December 3, 1883.

of bromide, the pulse was fuller and stronger, the temperature a little above the normal. The urine drawn by the catheter was about the same in character and less than two ounces in quantity. The eyelid was slowly closed once on touching the conjunctiva, but only after repeated efforts at rousing the patient. As nothing could be felt in the rectum, and efforts to feed by the mouth remained fruitless, the enemata were continued.

The faradic current was then employed, one pole being placed at the feet and the other at the hands; again the current was run from the back of the neck to the lower part of the abdomen and in various directions. The same treatment was continued, and the patient remained asleep and unconscious, though evidently gaining, till the 10th of May, when the eyelid began to answer irritation of the conjunctiva pretty constantly. A few days later the legs would draw up on sharply irritating the feet, and the bowels were moved by an enema. On the 12th he could be fed by the mouth, though the act of swallowing was slow, and took place only after repeated urging on the part of his attendants. He quickly relapsed into sound sleep after being roused. During the next day or two he moved his legs a little in the bed and coughed slightly. On the 15th he remained awake a good part of the daytime and voluntarily moved about in the bed. He could not hold a cup or any article in his hands nor feed himself, though he could make slow, awkward movements with the hands and fingers when requested to do so. The unpleasant odor of the breath increased in intensity till about the 6th of May, when it began to diminish, and by the 15th had entirely disappeared. The catheter had to be employed till this date (the 15th), when he passed his water voluntarily; at no time was it necessary to use the catheter more than once in the twenty-four hours, so little urine was secreted. The bladder contracted very slowly indeed, and it was only after calling attention to the matter that the urine was passed at first. The throat remained dry for some days after the swallowing of food was resumed. The legs could be moved before the arms and the feet could always be manipulated better than the hands, which did not recover the power of executing such complicated movements as feeding himself, buttoning the collar, and so forth, for a fortnight or more after he was thoroughly awake.

The first reflex observed was the eyelid on irritating the conjunctiva, next the facial muscles, and then the legs and other parts of the body; the hands and arms apparently last. About the 12th he would mutter a few words unintelligibly when strongly roused; they had a far-off, tired, sibilant sound, as is often observed in severe illness with dry lips and tongue, and it seemed to be a difficulty of articulation from incomplete muscular control; later a wrong word was sometimes used or a whole one forgotten. The senses of taste and smell seemed to be blunted for quite a time; sight and hearing were apparently not much affected. No cutaneous eruption was observed at all, though the skin had the dusky, dirty color mentioned above.

The patient lay sound asleep from April 25th till May 12th, a period of eighteen days, and for three days longer was asleep most of the time.

The treatment consisted of the exhibition of nutritive enemata, electricity, strychnia, alcoholic stimulants, diuretics, frictions of the skin, and baths, quinine, iron, and, later, cod-liver oil. Altogether 1890 grains, or about four ounces, of bromide of sodium were taken in one week.

The patient assured me the latter part of the month of May that he had lost all desire to resume his morphia, but he was left in such an apathetic state from his bromide that I felt that his statement was of little value then. I understand that he faithfully kept his promise not to use morphia for several months, but that he resumed it again, I know from having been called to him later. As I had little hope of doing him any permanent good, I referred him to Dr. C. F. Folsom. Since then, within two years, I have received notice from a "specialist" in Lawrence of his "permanent cure." Yesterday I called at the house where he lived, and learned that he had resumed his morphia and was taking with it at the same time small doses of atropia. He is entertaining the idea of beginning another "cure."

It has fallen to my lot to treat but few cases of morphia or opium taking. Those whom I have seen have mostly been at the Carney Hospital, where we could perfectly control their movements. The chief difficulty the patients have experienced has been a restlessness and sleeplessness which was at first hard to control. The opiate has been left off by rapidly diminishing the dose during the course of a week. I have never seen a very bad case, and so am little able to judge of the comparative merits of the method by Mattison and the ordinary ones. That his method as laid down in the paper referred to is not devoid of danger in some cases I am convinced. In fact, I am told of a fatal result in one case treated by the gentleman himself. That, properly watched, and the drug suspended when the patient becomes soporose, and elimination encouraged, it may prove of some service, I should think possible.

REPORT ON THEORY AND PRACTICE OF MEDICINE.

BY GEORGE B. SHATTUCK, M. D.,
Visiting Physician Boston City Hospital.

I.

COMA (THE SO-CALLED DIABETIC COMA) THE RESULT OF AUTOCHTHONOUS INFECTION THROUGH ABNORMAL PROCESSES OF DECOMPOSITION.

Last year[1] we gave an abstract of an important contribution from Dr. Fr. Th. Frerichs to the clinical history of the so-called "diabetic coma" and of sudden death in diabetes, in which he describes three quite different forms of sudden death in diabetes arising from different causes not understood, the acetonuria, when present, being regarded merely as a symptom. Since then Dr. H. Senator, in an address[2] before the Berlin Medical Society, has approached the subject from a still broader point of view, and argues, not only with Frerichs, that the term acetonæmia should be discarded, but that the adjective "diabetic" should be given up as in any way characterizing the picture, and that we should retain simply the term Coma from Self-Infection. Senator is led to take this position from having on various occasions observed much the same picture as that presented in "diabetic" coma in several other diseases, and notably in pernicious anæmia. He acknowledges the same ignorance as Frerichs as to the

[1] Journal, vol. cviii., p. 295.
[2] Zeitschrift für Klinische Medicin, vol. vii., p. 235, 1883.

nature of the poisonous products evolved within the economy, but does not think that they should be regarded as peculiar to diabetes. There are probably a number of these products, and it is also probable that one or more of them are common to several different diseases.

Senator sums up his consideration of the subject in the following propositions: —

(1.) Acute and chronic dyscrasias may arise not only by the retention of normal excreta, but also by the absorption of abnormal (poisonous) products of metamorphosis formed in the body itself, as well as by an abnormal collection of otherwise common substances.

(2.) The most common source of such autochthonous dyscrasias springs from anomalies of the digestive apparatus, and next from diseases of the bladder[1] and from extreme anæmias.

(3.) The consequences of such dyscrasias impress themselves especially upon the nervous system and the kidneys.

(4.) Next to uræmia the most characteristic of these acute nervous affections is the group of symptoms described by Kussmaul as "diabetic coma," the cause of which is to be sought in various toxic agents.

(5.) This group of symptoms of Kussmaul's may develop itself in the course of other serious maladies besides diabetes mellitus, as, for instance, in pernicious anæmias, and is not necessarily associated with the development of the wrongly so-called "aceton reaction" of the urine, the red reaction to chloride of iron.

COMA CARCINOMATOSUM.

Under the above title v. Jaksch,[2] Professor Nothnagel's assistant, contributes to this subject of "coma from self-infection" a case of carcinoma of the stomach in which death was preceded for seventy-four hours by a coma resembling in all respects the "diabetic coma," the urine containing aceton and diacetic acid in large quantities, but no sugar. The patient's strength was good at the time the coma made its appearance, and the cachexia was not marked. At the autopsy the kidneys were found to be healthy, and although changes were present in the lungs they were not of a character to account for the coma and peculiar respiration; such pulmonary changes, however, suggest Penzoldt's view that deficient excretion by the lungs — the usual channel — favors the poisonous action of the aceton upon the economy.

V. Jaksch had previously seen three cases of diabetes terminating in coma, and, although in each of these cases the pathological conditions revealed by the autopsies were entirely different, the symptoms preceding death were the same. In these cases, also, diacetic acid was present in the urine in large quantities for a considerable time. V. Jaksch himself has elsewhere[3] reported numerous instances of diaceturia unattended by coma, but in regard to these he states that the diaceturia was present only during a limited period of a few days, and accompanied by high fever. Whether the lungs were crippled in any of these he does not state. He assumes a non-committal attitude as to the connection of the diaceturia with the coma, and is engaged upon a further study of the subject.

In a previous paper,[4] the result of studies in the chemical laboratory at Prague, v. Jaksch divides pathological acetonuria (a small quantity of aceton is common in the urine of health) into four forms: (1) febrile acetonuria; (2) diabetic acetonuria; (3) acetonuria in certain forms of carcinoma, of which he had observed three cases at that time, ending in rapid dissolution though not in coma; (4) acetonuria resembling that present in the so-called acetonæmia of Kaulich and Cantani.

ACETONURIA. IS ACETON A POISON CAUSING INTOXICATION AND COMA.

Professor Penzoldt,[5] of Erlangen, not satisfied with the negative conclusions drawn by Frerichs from the laboratory studies of his assistant, Dr. Brieger, as to the poisonous properties of aceton, pursued the subject by further experiments upon rabbits. Frerichs found that large quantities of aceton could be introduced into the circulation of men and of dogs without visible effect, and concluded it was probably an innocuous resultant of a chemical process, although decided effects were produced upon rabbits, Penzoldt finds with rabbits that by retarding excretion, which takes place largely through the lungs, after its exhibition intoxication, hebetude, and coma follow; he also obtained less marked effects without influencing excretion. The disabling effect of diabetes at certain stages upon the lungs is well known, and Penzoldt's experiments indicate a legitimate comparison between uræmia attendant, under suitable conditions, upon renal incompetency and acetonæmia attendant, under suitable conditions, upon pulmonary incompetency. Penzoldt merely claims, as the result of his study, an increased probability, but by no means a proof, that aceton is an active agent in producing diabetic coma.

Dr. Mackenzie, on the other hand, in commenting on the analysis of the cases at the London Hospital (printed below) says: There is another circumstance that influences the occurrence of coma, though I am not aware that any one has drawn attention to this point, and that is freedom from, or only slightly developed, affection of the lungs. Thus in my series, in the nineteen fatal cases, the lungs were found after death unaffected in seven; in three, in which there was no necropsy, there were no signs of disease in the chest during life, and the mischief in the lungs was only recent in four; so that there was either no pulmonary disease, or only recent, and in some slight mischief in fourteen out of nineteen cases of diabetic coma. This has very important prognostic significance, for when well marked signs of disease of the lungs are discovered in a case of diabetes the probability is that the case will assume the characters of a rather rapid form of (pneumonic) phthisis, the sugar lessening as the pulmonary disease advances, and usually disappearing from the urine prior to the death of the patient. On the other hand, when pulmonary disease is absent or slight the occurrence of coma is more to be feared, especially the younger the patient, and the more acute the disease. It is necessary, in order to understand the pathology of diabetic coma, to consider its mode of oncoming and special characters.

ANALYSIS OF FATAL CASES OF DIABETES AT LONDON AND GUY'S HOSPITALS.

DR. STEPHEN MACKENZIE,[6] with the assistance of Dr. Gabbett, medical registrar, has recently analyzed the records of all the fatal cases of diabetes in the

[1] Sir Andrew Clark's catheter fever?
[2] Wiener Med. Wochschr., Nos. 16 and 17, 1883.
[3] Berliner Chemische Berichte, xv., H. 11.
[4] Zeitschr. f. klin. Med., v., p. 346, 1882.
[5] Deutsches Archiv für klin. Med., vol. xxxiv., p. 127.
[6] British Medical Journal, April 7, 1883, page 655.

London Hospital during the last eight years and a half, and the results are given in the following table: —

Analysis of all the Fatal Cases of Diabetes in the London Hospital, from the beginning of 1874 to Midsummer, 1882.

Death by coma; no gross disease found post mortem			7
Death by coma; no post-mortem examination	No signs of pulmonary or other visceral diseases during life	3	4
	With pulmonary disease during life	1	
Death by coma	Recent pneumonia or phthisis	4	8
	Old pneumonia or phthisis	4	
Cerebral hæmorrhage			1
Cerebral meningitis; coma			1
Cerebral tumor			1
Spinal cord disease and phthisis			1
Stricture of urethra; suppurative nephritis; coma			1
Scrofulous nephritis			1
Pneumonic phthisis			9
Scirrhus of pancreas; sudden collapse			1
Gangrene of foot; death rather sudden			1
Dermoid ovarian cyst; calcified mesenteric glands			1
			37

Dr. Frederick Taylor[1] gives an analysis of fatal cases of diabetes at Guy's Hospital as follows: —

Coma	No visceral lesions	14	26
	Visceral lesions inactive	3	
	Visceral lesions active	7	
	No post mortem	2	
Coma (diabetic?); renal disease			3
Pneumonia; influence of coma doubtful		1	3
Coma absent; no post mortem		2	
Phthisis, pneumonia, Bright's disease, peritonitis without coma			11
			43

French clinicians seem to meet with diabetic coma but rarely, and are inclined to regard the greater number of cases reported from Germany and England as due to the greater consumption of alcohol.

SUMMARY.

As the result of the contributions of Frerichs, Senator, v. Jaksch, Penzoldt, and others, the following statements may be made: —

(1.) The so-called "diabetic coma" is only one of several similar forms of intoxication in different diseases.

(2.) Aceton, or diacetic acid,[2] may still be proved to be a poisonous agent in the production of this condition, but it can in any case be but one of a number of such agents evolved within the system, and the name "acetonæmia" is unsuitable at present. Other substances, it should not be forgotten, also give the red reaction to chloride of iron.

(3.) Certain pathological conditions (of the lungs?) *may* be necessary to allow the poisonous action of diacetic acid upon the economy.

(4.) A better knowledge of the whole subject of the formation of poisonous agents within the economy under favorable conditions may reasonably be expected from physiological chemistry, and of their mode of action from further clinical observation.

(5.) The physiological hypotheses explanatory of the sense of fatigue as being the result of such agents, and the evolution of the so-called "ptomaines" in dead bodies point in this direction.

HEREDITARY POLYURIA.

M. Weil[3] reports a striking instance of polyuria as a family characteristic. He investigated the medical history of ninety-one members of the family of a patient, the subject of polyuria (diabetes insipidus), of whom seventy were living at the time, and found that no less than twenty-eight were polyuric. These polyurics had, as a rule, enjoyed good health, and many reached advanced age without any treatment. Weil expressly excludes imitation (canine polyuria) as an explanation in these cases, but it is difficult to avoid a suspicion of it.

MYXŒDEMA AND CRETINISM AS DEPENDENT UPON CHANGES IN THE THYROID GLAND.

At a recent meeting[4] of the Clinical Society of London (November 23, 1883) the exhibition of a typical case of myxœdema in a female by Dr. Drewitt gave rise to a discussion, and especially to some remarks by Dr. Felix Semon, who was present, which were certainly interesting, and may eventually throw more light upon the now obscure ætiology and pathology of this disease, which clinically is already pretty accurately mapped out. The gross resemblances of myxœdema and cretinism have struck many observers, and Sir W. Gull in describing the former disease, in 1873, was so much impressed by them that he termed it "a cretinoid state supervening in adult life in women," his cases having occurred — as is most often the fact — in women and those well advanced in the child-bearing period. Since then atrophy of and changes in the thyroid body have been observed by Dr. Ord, to whom we owe the name myxœdema, and others incidentally in not a few cases of the disease.

At this meeting of the Clinical Society Dr. Semon referred to a paper by Dr. Kocher, Professor of Surgery at the University of Berne, read at the twelfth Congress of German Surgeons held in Berlin last April, on the Extirpation of Goître and its Consequences. His experience was based upon 101 total or partial extirpations, and he discussed in the second part of the paper the consequences of the operation. His attention having been called by the subsequent medical adviser to the marked cretinoid condition of a patient upon whom he had operated some years previously, in 1874, he was so much struck by the extraordinary changes which had taken place that he immediately communicated with all those upon whom he had operated to secure an examination. He was able to obtain the attendance of only thirty. In sixteen of these cases a partial extirpation only had been made, that is, one lobe with or without the isthmus had been removed. In all the cases belonging to this category the result of the operation had been an excellent one, that is, the dyspnœa for which the partial extirpation had been performed had disappeared, and the general health had suffered in no respect. Matters, however, were entirely different with regard to the eighteen patients on whom total extirpation of the thyroid body had been performed, and who put in a personal appearance. Of these eighteen, two only showed an undeteriorated, or even improved, state of health. But it was a most remarkable circumstance that in one of these two cases a small accessory thyroid gland had undergone a hypertrophic change, and that in the other a recurrence of the goître had taken place. All the remaining sixteen patients showed more or less considerable derangement of their general health, the changes being much more developed in the oldest cases than in those more recently operated upon. These changes were therefore of a distinctly progressive character. As to the nature of the changes themselves, they were, in the order as related by Professor Kocher, the following:

4 Lancet and Times and Gazette, December 1, 1883.

A few months after the operation early fatigue, weakness, and sensation of heaviness in the limbs were complained of. In many cases these were preceded by actual pains in different parts of the body. Soon afterwards a sensation of coldness, especially in the extremities, was superadded. In winter time the hands and legs swelled, became bluish-red and cold, and the patients suffered from chilblains. The mental activity decreased; thought, speech, and movements became slower. At the same time the patients were themselves painfully aware of these facts. Simultaneously with the above symptoms swellings of the face and body made their appearance. They were sometimes at first only transitory, but soon became lasting features. The parts most and earliest affected were, as a rule, the infra-ocular region and the eyelids, which showed a somewhat transparent swelling; later on, the nose became thick, the lips coarse, hands and feet swollen, and the waist stouter; the skin became dry, desquamated a little, was infiltrated, and its elasticity lost; it could only be lifted in thick folds; the hair fell out. A most marked symptom in the more progressed cases was anæmia. Examination of the blood showed a relative richness of leucocytes, inasmuch as the number of the red blood corpuscles was greatly diminished. In the cases in which the patients at the time of the operation were still growing the development became most markedly arrested after the operation. Rarer symptoms were slight dysphagia, giddiness, and headache. Ophthalmoscopic examination, made in a number of cases by Professor Pflüger, did not reveal anything abnormal beyond remarkable narrowness of the arteries. Professor Kocher concluded his description, of which the most prominent features only were given in this epitome, by the remark that the relationship of the above complexity of symptoms to idiocy and cretinism was unmistakable. Being himself unaware of the existence of myxœdema, he proposed for the affection he described the name of cachexia strumipriva.

Dr. Semon pointed out that observations similar to Professor Kocher's had been made by Professor Revardin, of Geneva; that scarcely a symptom was present in myxœdema which was not met with in the cases of total extirpation, and, on the other hand, one symptom only had been observed in a certain number of these cases which was not present in myxœdema, namely, the arrest of the growth of the body after total removal of the gland in children, but this was explicable by the fact that myxœdema was essentially a disease of adult life. Professor Kocher's observations seem to indicate that there are three conditions closely allied to each other, and having in common either absence or probably complete degeneration of the thyroid body, namely, cretinism, myxœdema, and the state after total removal of the thyroid body.

A committee should be appointed by the Society to investigate and report upon this subject. Its report would naturally be awaited with much interest. In the course of the subsequent discussion of myxœdema Dr. Ord said in regard to treatment that in more than one case he had recently seen progressive improvement up to apparent cure under jaborandi; in about fifteen other cases he had seen also progressive improvement under this treatment, and he now used it in all cases, giving the tincture of jaborandi in half-drachm and drachm doses for months. Others, however, have been much less fortunate.

In connection with the subject of myxœdema it may not be amiss to record, as a matter of bibliography, the report of another typical case by Dr. Robert Kirk.[1] The patient was a woman in middle life who had borne six children, and been subjected to a good deal of suffering, mental, moral, and physical, a history which corresponds with a large number of previously reported cases. There had been a syphilitic exposure, which is an exceptional feature and may be considered incidental. All the other clinical features correspond closely with the type of the disease as now recognized.

III. ACUTE GONORRHŒAL RHEUMATISM.

Dr. Davies-Colley[2] records a number of cases of this affection, varying somewhat in character and in their history. The obstinate resistance to treatment and chronic course of some of these rheumatoid cases make welcome any well-considered contribution to their ætiology and treatment. The present writer uses the limiting adjective in so wide a sense that it should not be understood that the discharges from the genital organs which give rise to these inflammations are necessarily gonorrhœal; he suspects that a balanitis or even a leucorrhœal discharge may be sufficient cause. His experience coincides with that of several French observers as to the not infrequent occurrence of cardiac complications, especially in the chronic cases.

He believes that several distinct affections are often confused together under the name gonorrhœal rheumatism, which he enumerates as follows: —

(1.) *Gonorrhœal synovitis*, a chronic affection, occurring in the male, generally in the knee-joints. Very rarely it is acute, and goes on to suppuration.

(2.) *Gonorrhœal arthritis* (attacking especially the ligaments), an acute affection, occurring in the female quite as often as in the male; as a rule, attacking at the outset several joints, and afterwards confined to one, most frequently the elbow-joint, affecting especially the fibrous tissues of the joint, and only secondarily the synovial membrane and cartilages.

(3.) *Gonorrhœal inflammation of fibrous structures not connected with the joints*, for example, the plantar fascia, sclerotic, iris, the peri- and endocardium; this gonorrhœal inflammation of the plantar fascia sometimes occurs in the acute form. Inflammation of the first three structures usually occurs in connection with chronic gonorrhœal synovitis. In the last two situations inflammations seem to be generally associated with gonorrhœal arthritis.

With regard to the second class his remarks are summarized in the following résumé: —

(1.) It usually occurs during the acute stage of gonorrhœa, or some purulent discharge from the genital organs, in adult patients under middle age.

(2.) It occurs as often in females as in males, if not more often. Of twelve cases recorded by the writer nine were in females.

(3.) It may attack any joint, but most often the elbow-joint. Eight of the writer's twelve cases were in the elbow.

(4.) At first it attacks several joints, like acute rheumatism, and then confines itself, as a rule, to one.

(5.) Its seat is the fibrous tissue of the joint. There are great œdema, redness, pain, and tenderness. The ligaments are softened, and the cartilage may be disorganized. There is but little synovial effusion, and constitutional disturbance is but slight.

[1] Glasgow Med. Journ., January, 1884.
[2] Guy's Hospital Reports, vol xli., p. 187, 1838.

(6.) It may be confounded at first with acute rheumatism, later on with phlegmonous erysipelas, bursitis, lymphangitis, phlebitis, gout, and pulpy disease of the synovial membrane.

(7.) It rarely, if ever, suppurates, but is especially prone to set up fibrous anchylosis.

(8.) The best treatment is to cure the discharge, keep the joint perfectly still, and apply uniform pressure as long as the acute stage lasts, and then to use passive motion.

(To be concluded.)

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

FEBRUARY 13, 1884. Meeting called to order at eight o'clock. DR. R. T. EDES, chairman, presiding. The records of the last meeting were given in summary, and approved.

The paper of the evening was presented by DR. S. W. ABBOTT, Health Officer, Massachusetts State Board of Health, Lunacy, and Charity, on

MODERN LEGISLATION IN REGARD TO THE ADULTERATION OF FOOD AND DRUGS,

which is printed in full on page 241 of this number of the JOURNAL.

DR. B. F. DAVENPORT, State Analyst, then described the means employed in the detection of impurities in various medicinal substances as follows: —

As analyst under the Adulteration Act I have, as the result of my first year's work, reported to the State Board upon 680 samples of about 100 different kinds of pharmacopœial drugs, of which I found 284, or 41.76 per cent., to be adulterated within the meaning of that act. This defines as an adulteration in drugs, including all medicines for internal or external use, antiseptics, disinfectants, and cosmetics (1) if when sold under or by a name recognized in the United States Pharmacopœia it differs from the standard of strength, quality, or purity laid down therein; (2) if when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia or other standard work on materia medica, it differs materially from the standards of strength, quality, or purity laid down in such work; (3) if its strength or purity falls below the professed standard under which it is sold.

Those drugs have principally been selected for examination which were of the greatest importance as medicines, and which were known to be especially liable to vary from the standard quality, the profit of debasement being great, and detection thereof difficult from requiring special technical knowledge.

Of chiefest importance, therefore, are opium and cinchona bark, with the many preparations made therefrom.

Of the forty-six samples of powdered opiums examined hardly one of the not evidently reduced samples fell below the twelve per cent. of morphine, the minimum limit of variability allowed by the United States Pharmacopœia, 1880, and but one exceeded the maximum limit of sixteen per cent. Thus the limits of the United States Pharmacopœia seem to cover all fair samples likely to be found in our market, of which the average morphine content is about fourteen per cent. The 1880 Revision of the United States Pharmacopœia seems, upon a superficial view, to have raised the minimum limit of morphine strength of powdered opium two per cent., but it is not really so. The minimum limit of twelve per cent. required by the Revision of 1880 is by an excellent process of assay, in which all the requirements are given in full detail, while the minimum of ten per cent. required by the Revision of 1870 is by a totally different process in which many of the details needed for obtaining any definite results are totally omitted. For instance, the concluding sentence of the method is, when speaking of the crude crystals which have been obtained, "To purify these boil them with two pints of alcohol until they are dissolved, filter the solution while hot through animal charcoal, and set aside to crystallize." Now according to my own experience in working upon an average opium this amount of alcohol of that strength will not dissolve all the morphine crystals obtained, but it requires about half as much more alcohol. Then the amount of the animal charcoal to be used is not mentioned, a very material point considering that it absorbs quite a per cent. of the morphine, which cannot be afterwards all recovered from it even by repeated additions of boiling alcohol, yet the 1870 United States Pharmacopœia does not provide for the addition of the alcohol even once. Then there is no limit given of the time to set it aside to crystallize, another very important defect, considering that the given amount of alcohol would hold in solution, even when cold, about one quarter of all the morphine from a ten per cent. powder. All this would be lost to the assay unless the alcohol be set aside long enough to deposit it by evaporation. It can thus be very readily seen that the process of assay by which the United States Pharmacopœia, 1870, required a powdered opium to yield at the least ten per cent. of morphine might be honestly conducted so as to require a considerably higher morphine per cent. than the United States Pharmacopœia, 1880, requires for its twelve per cent. by a very definite method. Conducted, however, even to the best advantage for the sample of opium, I think that the two standards will be found to be just about the same. In other words, that although the Revision of 1880 seems to have raised the minimum standard for powdered opium two per cent. it has not really raised it at all.

Now in regard to tincture of opium there prevails much unfounded apprehension on account of the great supposed increase in its strength. This, according to the last edition of the United States Dispensatory, is not sustained by the real facts. It is founded, I believe, principally upon the assertion of Dr. E. R. Squibb that he will, since the last Revision of the United States Pharmacopœia, put now six grains of morphine into one fluid ounce of his laudanum instead of only four grains as formerly, thus making an increase of fifty per cent. in *his* morphine strength, according to the Dispensatory, "allowing the opium to be wholly exhausted of its active principles, one grain would be represented by very nearly eleven minims. According to the United States formula of 1880, while in the United States Pharmacopœia, 1870, one grain was represented by 12.8 minims." This represents an increased strength of only fourteen per cent. of morphine between the

tincture opii, United States Pharmacopœia, 1870 and 1880, that is, the grain dose is given in about twenty-two drops instead of twenty-five as formerly. This difference of three drops only is a less variation in quantity than would probably be made by successive attempts of the same or different persons to drop out the old twenty-five drop dose. So that I think physicians need not under *ordinary* circumstances have any anxiety as to whether it will be a tincture made according to the United States Pharmacopœia 1880 or 1870 that will be dispensed in their prescriptions. Yet it would be well, for a while at least, to write (U. S P., 1880) after the name of any pharmacopœial preparation which physicians particularly desire to be *surely* of the full strength, as what would thus be likely to be dispensed would more probably be of the proper quality, and the writing thus would show the pharmacist that the physician was observant and particular in such details. This is a much more reasonable way than writing the name of any particular manufacturer after pharmacopœial preparations, for it allows the pharmacist to put up his own or any one's make that he is ready to guarantee, but holds him to the full responsibility of that which he dispenses. He could not, however, be thus held if he put up a particular make which was ordered, even if this was not more than a quarter of the full proper strength.

In my examination of 100 samples of laudanum collected from all over this State, the pharmacopœial limits being between 1.2 and 1.6 per cent. of morphine, I have found samples containing all the way from 0.33 to 1.87 per cent. of morphine, thus one six times as strong as another, and with specific gravity varying from 0.921 to 0.997. Four samples exceeded the 1.6 per cent., and eighty-two fell below the 1.2 per cent. The average per cent. was 0.965, and the specific gravity 0.953. Forty-five samples contained about one per cent. of morphine as was required by the United States Pharmacopœia, 1870, if assayed by the modern process of United States Pharmacopœia, 1880. The best pharmacists of this city are now generally making up their tincture to the average United States Pharmacopœia standard of 1.4 per cent. morphine, or about the six grains to the fluid ounce. The ten samples of morphine salts examined have all come up to standard.

Of citrate of iron and quinine forty samples were examined, and were found to contain all the way from 3 per cent. to 14.37 per cent. of quinine, the present United States Pharmacopœia requiring 12 per cent. only, while the previous one required 16 per cent. Of these samples 82.5 per cent. fell below the present standard, two makers alone having been found to have their preparation generally fully up to standard. Of about thirty samples of quinine salts examined 28.5 per cent. contained an excessive amount of the cheaper cinchona alkaloids.

Only two out of a dozen powdered jalap samples contained the proper amount of resins, while out of ten samples each of the bromide and iodide of potassium not one came up to standard; trade absurdly demanding that the crystals should be, not translucent and colorless, and therefore *possibly* pure, but opaque and porcelain white, and therefore *of necessity* impure, with excess of alkali, which renders them unfit for use with alkaloids, syr. ferri iod., or any other like combination which might be desired.

DR. EDES remarked that by employing the more recent manufactures by Squibb the physician would obtain a much larger dose than in the earlier preparations. In the case of tincture of opium the present preparation contains fifty per cent. more opium than the former tincture.

DR. GEORGE B. SHATTUCK asked what were the poorest results obtained by analysis of laudanum and citrate of iron and quinine.

DR. DAVENPORT stated that the most common result was to find a content amounting to from one fourth to three fourths the amount required by the Pharmacopœia in analysis of tincture of opium, and in citrate of iron and quinine any amount from one third to the normal quantity.

DR. MORTON PRINCE suggested that if the firms who manufacture and dispense standard goods were made known to the profession it might be the means of protection from imposition on the one hand, and aid in driving the spurious articles out of the market on the other hand, both of which objects it would seem desirable to accomplish.

DR. C. HARRINGTON, of the Harvard Chemical Laboratory, gave a somewhat detailed account of the analyses of various articles of food under the auspices of the Board of Health, as follows: —

About three hundred samples of milk have been subjected to analysis. The milk was obtained from all parts of the State, and was secured in each instance from the regular supply furnished to customers. Milk should contain under normal conditions about thirteen per cent. solids. In some specimens the solids were present only to the extent of nine per cent. The first one hundred samples of milk and the greater part of the second and third hundreds were obtained in Boston, and of these samples more than seventy per cent. were adulterated. The milk from the western parts of the State, particularly from Berkshire County, was found to be uniformly freer from adulteration than that from the eastern counties. The poorest samples of milk were invariably those obtained from the shops and groceries in which it is sold at retail. Milk directly from the cart was always of better quality. In certain large towns the milk supply was far superior to that in certain other towns of equal population. Thus Lawrence, Worcester, and Springfield enjoy purer milk than do Lynn, Chelsea, and Somerville. In Worcester the solid constituents of milk averaged from twelve to sixteen per cent., while in ten cases which were prosecuted the proportion of solids was in none more than nine per cent.

Various articles of food were found to be adulterated in fifty per cent. of the samples. Butter was occasionally found adulterated with oleomargarine. Tea was adulterated to a greater or less extent, one sample containing twenty-six per cent. of sand. One specimen of coffee was found to contain twenty per cent of chicory. Two hundred samples of spices were examined and all were found to be bad. Of twenty-four samples of mustard only two were found to be good. Fifteen different brands of mustard in boxes were found to consist of wheat flour, and turmeric in a greater or less degree. Various samples of pepper were analyzed and found to contain chiefly only dirt. Spice mixture is found to consist mainly of similar material, and sells for forty cents per pound. Several specimens of pure olive oil from Leghorn were analyzed, and were found without exception to consist entirely of cotton-seed oil from the Providence Oil Company.

In cereals and bread no adulterations were detected. Bread contained neither alum nor copper. Some specimens contained an excess of moisture, but this can hardly be called an adulteration. Cocoa and meals, sago and tapioca were not found to be adulterated.

DR. J. C. WHITE asked the minimum standard of milk solids in cases which were prosecuted.

DR. HARRINGTON stated that no case had been prosecuted in which there was a solid content of eleven and one half per cent.

DR. WHITE alluded to a case in which no adulteration could have possibly taken place, in which the amount of solids reached only nine per cent.

In reply to a question, DR. HARRINGTON stated that none of the milk examined was rendered in any way injurious by adulteration, that nothing but the cream had been removed, and nothing but water had been added to it. Neither of these changes would make the milk directly injurious or dangerous.

MR. G. F. PIPER, attorney for the Board of Health, who was present by invitation, spoke as follows: —

Prior to the passage of the statute of 1882, entitled "An Act relating to the Adulteration of Food and Drugs," the legislation upon that subject was confined to fraudulent adulterations and adulterations injurious to health. The fraudulent conduct, or the guilty knowledge, or the fact that the adulteration was injurious to health, therefore, became elements, upon a complaint, which the government was bound to prove, and the great difficulty of proving these elements virtually made the statutes upon that subject a nullity. Very few prosecutions accordingly resulted. This form of legislation was not broad and stringent enough to reach the many cases of substitution of one article for another, or, as in the case of a drug, its manufacture below the ordinary standard of strength and purity usually adopted and recognized, or a case where some valuable constituent may have been removed and a poorer one substituted, and the many other various forms of commercial frauds existing. The statute of 1882 broadened and extended this class of legislation, its purpose being to reach all cases which the previous legislation did not reach.

In the case of drugs it adopts a standard and makes it an offense if the party selling sells an article varying from that standard, if sold under a name which carries with it a recognized standard. If the drug sold is one recognized in the United States Pharmacopœia, it adopts that standard. For instance, tincture of opium, according to the Pharmacopœia of 1880, contains 1.20 percentage of morphine. A druggist therefore who sells tincture of opium of less morphine strength than that standard is liable to prosecution.

If the drug is sold under a name not recognized in the United States Pharmacopœia, but which is found in some other Pharmacopœia or other standard work on materia medica, it would be an offense under the statute if it differed materially from the standard of strength, quality, or purity laid down in such work. And again, it would be a violation of the statute if the strength or purity of the drug fell below the professed standard under which it was sold.

In the case of food, the statute defines also what shall be deemed an adulteration; for instance, mixing any substance or substances with the article so as to reduce, lower, or injuriously affect its quality or strength; substituting any inferior or cheaper substances; abstracting any valuable constituent, or selling an article under the name of another article.

The statute absolutely prohibits the sale of any article of food or any drug adulterated within the meaning of the act.

The element of fraudulent conduct, or guilty knowledge, or criminal intent, does not enter into the offense. If the party selling violates any of the provisions of the statute he is liable to the penalty therein set forth, without regard to the question whether he knew or did not know what the article was he sold. For the protection of the public, the statute imposes upon the tradesman the most extreme caution in selling his goods. He is bound to know what he is selling. This, certainly, is no injustice, for the purchaser buying and paying for a pure article is entitled under the law to the greatest protection.

The tradesman by the exercise of proper caution can inform himself of the nature of the article sold, while the purchaser must rely, and does rely, wholly upon the good faith of the tradesman. There is every reason, then, why the burden should be placed upon the seller and not upon the purchaser.

The statute imposes the duty of enforcing the provisions of the statute upon the State Board of Health, Lunacy, and Charity. The enforcement of similar laws, for example, the laws against the adulteration of milk, and the laws against the adulteration of vinegar, have heretofore been left with local inspectors, appointed by the different towns and cities throughout the Commonwealth. This mode of enforcing a law has proved generally to be an utter failure.

The local inspector is usually some individual who has been appointed for some political service rendered, who may have no qualifications for the office, and whose only purpose and desire often are to make the greatest money's worth out of his office. The salary is usually very meagre, and generally no appropriation is made for the expense of enforcing the law. Accordingly little work is usually done and the adulterator flourishes.

The milk inspector of Boston recently testified before the Legislative Committee on Public Health that he had made six hundred examinations of milk during the past year, and thirteen persons had been convicted of selling adulterated milk. His practice was, he said, to go around the city early in the morning, carrying with him his lactometer, and placing it in the milk he in that way decided whether the milk was adulterated. It is well known that this method of determining whether milk is adulterated is very unreliable and unsatisfactory. This may to some extent account for the few prosecutions and the condition of the milk market in Boston, in which, according to the statement of Dr. Charles Harrington, chemist to the State Board of Health, ninety per cent. of the milk sold during the past year was adulterated, and badly adulterated.

The State Board of Health, Lunacy, and Charity, by reason of the qualifications of its members and its freedom from local and political influences, is more likely to be a much more efficient agency to be intrusted with this work.

In November last the State Board commenced its prosecutions. The first prosecutions were against grocers and provision dealers in Boston for selling adulterated milk, and these were subsequently followed up by others.

Ten convictions have been secured.

Complaints were entered during the same time against several parties for selling adulterated tincture

of opium, and in one case for selling adulterated citrate of iron and quinine.

The analysis of the tincture of opium sold showed the following percentages of morphine: .38, .63, .79, .72, .81, where the Pharmacopœia standard of 1880 required 1.20. They were all convicted, with one exception, and in that case the adulteration was clearly proved, but the firm prosecuted testified that the tincture was sold by a young man in their employ who had no authority to sell, his duties being not those of a salesman but pertaining to another department. This firm escaped conviction in that way.

The first prosecution for selling adulterated tincture of opium was before the Central Municipal Court of Boston, and developed the question which Pharmacopœia was the standard by which these cases should be governed, whether that of 1870 or that of 1880.

The Pharmacopœia of 1880 was not published and in use in August, 1882, when the Food and Drug Act took effect. It was accordingly contended by the parties prosecuted that the Legislature must have had in view the standard of 1870, and that these cases should be tried and judged by that standard. On this first prosecution the tincture of opium was, in its morphine strength, below both the standard of 1870 and 1880, and the judge who tried the case found as a fact that the drug was adulterated, but did not rule upon the question which standard was in force. On the next prosecution before the chief justice of that court the question was again raised and presented, and a decisive ruling was made to the effect that the Pharmacopœial standard by which the drugs sold should be judged was that which was in use at the time when the sale was made, and accordingly ruled that the standard of 1880 must govern existing cases. This ruling has been followed by the other judges of that court.

On the prosecution for selling adulterated citrate of iron and quinine it appeared that the article sold varied from the standard percentage of the quinine according to the formula of the Pharmacopœia of 1880. The parties were convicted.

A prosecution was made against a dealer in vinegar, in Somerville, for selling a vinegar as a pure cider vinegar. The statute makes it an offense to sell as cider vinegar a vinegar not the legitimate product of pure apple juice, known as apple cider.

The chemist for the government testified that in his opinion the sample sold was a cider vinegar which had been watered. The chemist who was summoned by the defendant before the trial had been given full opportunity to test the sample. Upon the witness stand he testified that he had had a large experience in the manufacture and analysis of cider and cider vinegar, but he had in his experience never seen a cider vinegar with the small amount of acetic acid and residue which this sample contained. He further testified that the sample was to him very suspicious.

The judge, contrary to all precedents, ruled that it did not appear that any criminal intent existed or any fraudulent conduct. The counsel for the government suggested that it was not necessary for the prosecution to prove either elements, that the sale itself, under the statute, was a violation of law, and that no criminal intent, or guilty knowledge, or fraudulent conduct need be shown. He replied that that would be unconstitutional.

The defendant was discharged.

This principle has been decided time and again by our supreme court, and the ruling of the Somerville court in that respect was clearly and beyond question wrong.

I have been very much surprised at the position taken by the press of Boston in reference to these prosecutions. The reporters of three of our newspapers have told me that they have received orders not to report facts in reference to these prosecutions, and that articles that have been written by them for publication have been refused publication. I had supposed that in a matter of this kind that it was the duty of the press to advocate what seems to me to be the cause of the people. The purity of food and the purity of drugs should and must be a matter of great moment and importance. The reason of this course pursued by the press of Boston we may not know, but I think we can, each one of us, very clearly draw our inferences what that cause may be.

The physician is largely interested in the enforcement of this law. When he writes his prescription it is of the greatest moment to him as well as to his patient that it shall be filled out as he has written it, and according to the existing standard. A fixed standard is absolutely necessary, and the physician and the druggist must in unison adopt that standard.

At the recent hearing before the Legislative Committee on Public Health it was testified by one who had been a defendant in one of the prosecutions for selling adulterated tincture of opium that he did not believe in the Pharmacopœia, and he would leave it to the discretion of each druggist to fill out a prescription. Comment upon such a statement is unnecessary. Let, then, the physicians of Boston give their strong moral support and encouragement to the State Board of Health, Lunacy, and Charity in the enforcement of this law, and make it an efficient law, and not a dead letter.

(To be concluded.)

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES H. WILLIAMS, M. D., SECRETARY.

JANUARY 7, 1884. DR. E. G. CUTLER read a paper on a case of

PROTRACTED LETHARGY AFTER THE USE OF BROMIDE OF SODIUM

by an individual having the morphia habit.[1]

DR. BUNDY said that he had a case twelve years ago where the patient took two and a half ounces of bromide of potash with similar result; the patient was unconscious for two weeks, but gradually recovered. The disease was a habit of drinking whiskey and ether, but the bromide did not cure the trouble. There was entire loss of the power of coördination, and at the end of two weeks he was moved into another house without knowing it.

DR. CUTLER mentioned one fatal case where the drug was pushed to its limit, in which the patient sank and died in one week. In this case the kidneys did not work well.

DR. EDES referred to two cases reported by Dr. Schweig in the *New York Medical Record*,[2] in which

[1] See page 246 of this number of the JOURNAL.

[2] Vol. xi., page 841.

excessive doses of bromide of potash produced similar results to those reported. Anæsthesia of the conjunctiva is rare.

Dr. Folsom had seen a case where there was much physical depression, boils, etc. After excessive doses of bromide he gave large quantities of water to help eliminate the drug. After the effect passed off there was much insomnia. For three weeks after the taking of the bromide the patient had no desire for morphia, but it returned later. After this he had an interval of five months during which he gave up the morphia, but his suffering was so great that he began using it again, and says he shall never make another attempt to break up the habit. Dr. Folsom had seen cases where bromide of potash had been given for other purposes where the torpor had lasted as long as this. It seems to vary with different persons. In epileptics the bromides sometimes do good, but sometimes harm, as in the case of a young lady who was taking fifty grains three times a day without effect on the epileptic attacks, but who was suffering from the excess of bromide. When pushed to excess it may cause a mild form of silly mania.

Dr. Channing had seen cases of morphia habit where large doses of bromide of potash had been used, but without good result, and he considered the excessive doses as dangerous. He also thought chloral was not of much service in these cases.

After the shock of the bromide of potash passes off there may be a temporary relief, but the desire for opium returns. The treatment must be largely moral, and must depend on the patient. It is best to break off the opium as rapidly as possible, best in one week. Then bromides may be used occasionally for sedative effect.

Dr. Edes mentioned Laport, Indiana, as a headquarters for "morphia cures."

Dr. Davenport said that all the so-called morphia cures manufactured there contained opium, often in solution in glycerine, and colored with aniline. He spoke of the increase in the strength of the tincture from nine in one hundred to ten in one hundred, but said that the increase was not great enough to produce much effect in ordinary doses. He mentioned the assays which he had been making for the Board of Health of the strength of the tincture of opium sold in the shops. Variations had been found all the way from one quarter of the standard strength to fifty per cent. over this standard, but in the latter case a single druggist had made a mistake in compounding.

Dr. C. H. Williams read a paper on Intraocular Changes in Cases of Cerebral Tumor.

Dr. E. H. Bradford reported

A SUCCESSFUL CASE OF AMPUTATION AT THE HIP-JOINT.

The patient was a boy eight years old, whose hip-joint had been excised in July by Dr. A. T. Cabot for caries. The femoral shaft was found so extensively diseased that amputation was advised, but the parents' consent could not be obtained, and the patient's condition became gradually worse from long-continued diarrhœa. This, however, stopped in October, and in November amputation at the hip-joint was performed by Dr. Bradford. No shock followed the operation, and the boy steadily improved, at the present time, three months after the operation, having nearly doubled in weight, and being able to walk about with crutches freely. Sinuses persist from the pelvic disease, but the boy's condition is such as to justify the belief in a cessation of the carious process. Dr. Bradford mentioned that there were no less than forty-two methods described for amputation at the hip-joint. The chief anxiety is in regard to hæmorrhage. The method employed was suggested by Dr. C. B. Porter, who himself has employed it. The amputation is performed in two steps, — first an amputation of the femur as high up as is practicable, using Esmarch's bandage and tourniquet to control the bleeding. The vessels are then tied, and there is no fear of hæmorrhage while performing the second step, namely, the removal of the head and upper part of the shaft, which is done by a lateral incision and subperiosteally. The difficulty in disarticulation in the case reported was slight. Only a portion of the head remained. Where this is not the case disarticulation, as for excision, can be performed before the amputation is begun.

Dr. Cabot said the same operation might be applied to the shoulder-joint, for patients are often much benefited by the removal of these diseased parts and the constant drain on the system caused by their suppuration.

Recent Literature.

Hints on the Drainage and Sewerage of Dwellings. By William Paul Gerhard, Civil Engineer. New York: Wm. T. Comstock, 6 Astor Place. 1884.

This excellent work of three hundred pages contains much valuable information for all who are interested in the sanitation of dwelling-houses.

Physicians, householders, and plumbers will find in it many useful hints. The chapters on Traps, Plumbing-fixtures, and on the Removal and Disposal of Household Waste are especially full and well illustrated. The defects of various contrivances are clearly indicated, and modes of remedy suggested. The book contains nearly three hundred illustrations, which are sufficiently shorn of extraneous detail to render them intelligible to the non-professional reader.

Handbook of Eclampsia. By E. Michener, M. D. and Others. Philadelphia: F. A. Davis, Att'y, 1883.

This sextodecimo book of sixty-eight pages contains notes of forty-four cases of puerperal eclampsia, being "all which have occurred during the present century within a radius of several miles around Avondale, Chester County, Pennsylvania, so far as can be ascertained." The ostensible object of the book is the advocacy of blood-letting in all cases of puerperal eclampsia without discrimination.

Deference to the age of the chief author, who was an interne in a Philadelphia dispensary in 1816, and whose views of the pathology and ætiology of eclampsia do not conform to those held by modern authorities on this subject, forbids that freedom of criticism which the book should otherwise receive: and we will simply say that while we believe in the efficacy of blood-letting in certain selected cases, we do not believe in its indiscriminate use, especially in the cases of eclampsia

occurring post partum. We cannot recommend the manual even "to the young and isolated physician" to whom it is inscribed; but we heartily approve of the advice given on the last page that "for the last three months of her term" a pregnant woman "should be kept under the observation of a competent medical adviser." C. M. G.

Medical and Surgical Journal.

THURSDAY, MARCH 13, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

REPORTS ON CHOLERA FROM SURGEON-GENERAL HUNTER AND DR. ROBERT KOCH.

THE fifth cholera report of Dr. Robert Koch to the German government, this one from Calcutta, and the report of Surgeon-General Hunter to the British Foreign Office on cholera in Egypt, the essence of which is contained in a paper read by him before the London Epidemiological Society on January 9th last, have again turned medical attention to the discussion of this disease. Dr. Koch's report, which was first published in the *Deutsche Med. Wochschr.*, February 14th last, and in the Berlin daily papers of the same date, is being republished and commented on by the medical periodicals, and Sir W. G. Hunter's remarks were made the special subject of debate at the adjourned meeting of the Epidemiological Society held February 13th.

There is one thing in common between the report of the German and that of the English investigator, each seems pretty well satisfied that he has found what he went out to seek, and the results in each case confirm the investigator in the preconceived views with which he departed on his mission. Surgeon-General Hunter is probably but little more certain to-day that cholera is endemic in Egypt than he was when first commissioned by government to ascertain the cause of the outbreak last June; and Dr. Robert Koch, notwithstanding his really scientific cast of mind and methods of work, would probably have been more surprised and disappointed than he was prepared to be had not the Imperial German Commission confirmed and enforced, wherever cholera was actually to be found, the results of the study in the Berlin laboratory on the cholera intestines imported from India.

The two reports have at least one other thing in common, namely, that whatever coloring they may lend or appear to lend to the views advocated or expressed by the respective writers, neither the one nor the other can impress the impartial reader, of whatever nationality, — and we are sorry the influence of nationalities should be felt in such questions, — as by any means conclusive of the correctness or value of the positions assumed.

The similarity in the attitudes of the two investigators toward the common subject, cholera, ceases with their both having preconceived views confirmed by their investigations. Hunter asserts that cholera is a non-contagious disease (typhoid fever may also be called non-contagious); hence he disbelieves in the existence of a specific germ, and consequently in the necessity of importation, and therefore seeks for, and believes he finds, the cause and origin of epidemic outbreaks in the condition of the country itself, the disease being endemic. Telluric influences foster the disease as an endemic, and favorable climatic or meteorological conditions light up an epidemic. What he learned in Egypt convinced him that cholera had been continuously present there in one form or another at least since the great epidemic of 1865. The following curious extract from Lord Bacon concerning the climatic and telluric peculiarities of Egypt was unearthed for the benefit of Dr. Hunter: —

"It is recorded, by competent observers, that if you take earth from the side of the Nile, and protect it from wet or waste, and weigh it every day, you will find that it remains always of the same weight until June 17th, when it begins to increase in weight, and continues to increase in weight during the whole time that the river is rising. This can be due to nothing but the air, and this is the more extraordinary, because it has been observed that just at that date it is the habit of grievous plagues to make their appearance at Cairo."

The Surgeon General had previously expressed himself on the point thus: —

"The frequency with which atmospheric phenomena have been observed in connection with outbreaks of cholera leads to the conclusion that they stand in close relation one to the other. Whether that be as cause and effect is perhaps hard to say. It is probable that it is to a combination of certain conditions of a cosmo-telluric character, of air, soil, and water (filth, as in Egypt, being a powerful factor), that the development of an epidemic is due. Given, as in Egypt, endemic centres, the peculiar atmospheric state noticed would probably act as an exciting cause in the immediate production of the epidemic outbreak."

The German Commission went out, not to find the cause of any one outbreak of cholera, but to study the disease and to find its ultimate *causa causans*. Koch evidently regarded the disease *à priori* as specific — whether contagious in any degree or not — exhibiting a specific germ, whose habitat was probably the bowel; this may be fairly presumed from his general attitude toward other epidemic diseases, and from his investigations at the laboratory of the Sanitary Bureau at Berlin. Instead of studying the Egyptian *circumfusa*, Koch devoted himself to the *dejecta* and especially, among the internal organs, to the bowel. The limited Egyptian experience (twelve cases of cholera, and ten autopsies) confirmed the observations made at home in regard to the presence of a certain *bacillus* in the

walls of the small intestine without affording satisfactory proof of its specific character. The last and fifth report of Koch, dated Calcutta, January 7th, is based upon a further study of eight cases of cholera, and nine autopsies. The bacillus has continued a constant feature, and has been successfully isolated and cultivated, and its distinguishing characteristics carefully noted. Furthermore this bacillus has not presented itself except in the intestinal contents or walls of cholera victims.

The report offers no further evidence as to the relation of this micro-organism to cholera, and, though vague on that point, it is pretty plain that attempts to reproduce the disease by inoculation still remain unsuccessful. It is therefore in order to restrain excessive enthusiasm in regard to the "cholera-bacillus" of the small intestine, no less than it was in regard to the cholera microbion of the blood reported by the French Commission in Egypt, which Koch now with fine irony suggests in his report is probably nothing more nor less than the well-known "blood-plates," figured as far back as 1872 by Lewis and Cunningham in a report on microscopical and physiological researches concerning cholera.

It is not probable that the Germans will allow themselves to abdicate their judgment as to the bearing of Koch's observations, and we need not be overhasty to immolate ours in this country; the English are criticising Hunter's position very judicially; but it is pretty safe to predict that both Koch and Hunter will be ruled out of court by French scientists.

ACTINOMYCOSIS OF THE PERITONÆUM AND ABDOMINAL ORGANS IN MAN.

Five cases of actinomycosis affecting the peritonæum and abdominal organs are reported from Vienna by Dr. Adolf Zemann,[1] assistant at the Pathological Institute there. The characteristic fungus colonies were found in all cases both in the purulent contents of the abscesses and in the tissues of the affected parts. The number of previously reported cases is small. Ponfick collected sixteen in all of his own and others, and these were published in his monograph on the subject, which appeared in 1882. These cases Ponfick divided into two groups, those which recovered and those which were fatal. The former group consisted of cases where the malady made its first appearance on the jaws, — preferably on the lower jaw, — and spread downward along the neck to the clavicle. The second group of cases comprised those in which the process announced itself by pains in the limbs or, more generally, along the spinal column and neighboring parts of the back, succeeded by pneumonia or pleuro-pneumonia of the left lower lobe. In a few cases these pains precede a prevertebral gathering which becomes a psoas abscess.

These five cases now reported seem therefore to be, not only a considerable addition to the existing observations of a but little-known pathological process, but also to enlarge the clinical description of the disease. Some of these cases ran their course with fever and others without. Zemann concludes from his study of them that the important point in the diagnosis of actinomycosis is the discovery of the pathognomonic fungus. Apart from such identification the disease can neither be diagnosticated from the part affected nor from the course which it runs, since the process may be febrile and acute, or almost without fever and chronic; in which latter case it manifests itself as an induration, as a chronic inflammation of serous membranes, as an inflammation in the bones or periosteum, or as an inflammation attacking the internal organs. All of which is demonstrated by the varied points from which the fungus gains access to the body, and by almost innumerable complications attendant on its presence.

Zemann's cases certainly tend to show that by no means so simple a picture as that given in Ponfick's monograph will suffice to represent actinomycosis.

THE REFLEX EFFECT OF DEALING IN "FUTURES."

There can be no doubt that the character of the habitual mental occupation exerts a considerable influence upon the physical condition of men. That a very high degree of intellectual activity is not inconsistent with excellent general health and long life is a fact familiar to common observation, and is confirmed by published mortality records, from which it appears that the longevity of the members of the so-called learned professions is hardly exceeded by that of any other class in the community. It seems to be also well established that an alternation of the character of one's studies often is equivalent to a positive recreation. Thus we have recently met with the statement of an Englishman, eminent at once in the law and in literature, to the effect that after what would be a fair day's work in the former field he turned to his historical writing with a feeling of actual refreshment, even greater than that to be obtained from mental inactivity. Thus dividing his time he was able to accomplish, without fatigue, fifteen hours' work per day.

The amount of actual labor of which the human mind and body are capable under well adjusted conditions is certainly very great. In all men of affairs of whatever calling, it is of course unavoidable that anxiety (whose exhausting tendencies are generally admitted) should to some extent be present. But it seems to be the fact that so far as the uncertainty has to do with affairs which are controlled by one's own powers it is less wearing than when such affairs are independent of one's own control, and entirely the sport of extraneous chance. Thus while the conductor of a legitimate business project is, perhaps, working under a higher pressure than the student of a pure science, his calling is yet more favorable to longevity than that of the stock operator. And, indeed, it is, perhaps, not unlikely that the great stock manipulators, some of whom have certainly reached a

green old age, are more favorably situated in this respect than the smaller speculators, in that the former are really able to a considerable extent to make the market, and that to them Fortune is not altogether a blind goddess, but gives a knowing wink as she turns her wheel. Thus in judging of the effects of these occupations one should remember that even as many physicians are not given to dosing themselves, so some stock brokers do not themselves speculate. To buy and sell for the account of others, even to collect a wide "margin" from one's client, do not involve any personal risk-taking. If business is brisk the pool seller may be equally content whichever horse wins, and we believe that in certain other games of chance, however the cards turn, the "bank" makes its earnings without interruption. There may, then, be a class even of professional gamblers who while sitting in the very vortex of the giddy whirl are quite at rest in their own minds. Not so with those who are fairly in the current.

Of the moral effect of gambling, of course in this connection we have nothing to say. Its disastrous influence upon the mental and physical nature of its votaries was emphasized in a recent lecture by Dr. Crichton Browne, of England, on the Gospel of Recreation. Those amusements which depend for their zest upon the element of chance certainly have a strong attraction for the average man, as is shown by the frequency of betting on all sorts of subjects. The sporting papers and the sporting column of the daily press add fuel to this flame, which needs little to keep it alive. Dealings in futures are made easy by the widely published quotations of all sorts, and despite the heavy chastisement which has recently been inflicted on hundreds of small operators by the merciless depreciation of values, yet the public is still ready at every opportunity, whether at a club table, in politics, in athletics, or even over the great staple commodities of life, such as cotton, petroleum, or grain, to bet on events yet to occur. As a producer of intense emotional excitement perhaps no other amusement has the power of gambling, and it requires no demonstration that profound and repeated emotional excitement is a frequent precursor of nervousness, sleeplessness, and insanity, even if we do not go to the extent of Dr. Browne in attributing to this cause "numerous cases of dyspepsia, . . . heart disease, diabetes, paralysis, and apoplexy."

Dr. Browne, alluding to the effects of a vice or habit on the faces of those addicted to it, and quoting Mr. Francis Galton to the effect that the sight of a bundle of photographs of criminals will excite from their ugliness a sense of aversion or disgust in a spectator, says: "But the next best place to a prison in which to see the English physiognomy at its coarsest and worst is the platform of a London railway station on the day of a suburban race meeting, when the special trains are just starting. There may be seen a pushing, chaffing crowd of betting men, or bookmakers, and their dupes, with rascality stamped on their features in a way that cannot be matched in any other spontaneous assemblage of their countrymen. In almost every face may be discerned cruelty and greed, in many be recognized a hideous mixture of imbecility with low cunning, and in a few may be caught glimpses of infra-human or mere animal rapacity. There may be seen faces that are congenitally and radically bad, and with them others that bear the faded traces of better things almost blurred out, perhaps by the blotches of dissipation and the hard lines carved by this soul-destroying vice." A glimpse by Bulwer-Lytton, when a young man, in Paris, of his own face in a mirror after a night of successful gambling, was such a revelation to him, in its haggard and sinister lines, of the effect that gaming was exerting on his whole nature that he thenceforward abandoned it completely.

There is ground for the physician and hygienist as well as the moralist to discountenance that general devotion to hazard which, in public and private, characterizes so much of the city life of the day.

MEDICAL NOTES.

— A correspondent of the *Medical and Surgical Reporter* (March 1st) narrates a case where it seems tolerably certain that scarlet fever was transmitted by means of a letter. At least there is much less room for doubt than in many cases where such a cause is popularly assigned. The outbreak was in a country house half a mile distant from the nearest neighbor, and the family had occupied the house for three years; the children had not been away from the farm for two months, and no one had been in the house who had had the fever or been where it was. In fact, no case of the disease had been known of or heard of by the physician for some months anywhere in the county. It appeared, however, that the mother had received a letter from her brother only a short time before, stating that her brother's family had just lost a child with scarlet fever. This letter contained a photograph. The letter was received only seven days before the first child was taken sick, and the children all handled the letter and picture.

— The Faculty of the New York Polyclinic have been obliged by the increasing success of that institution to provide larger room, and have therefore purchased the extensive property heretofore occupied in part by them, which will be remodeled and fitted with amphitheatres for clinical work, well-furnished laboratories for chemical, histological, and pathological studies, and rooms for operative surgery and demonstrations in surgical anatomy. These increased facilities, taken in connection with the hospital appointments of the Faculty, enable the Polyclinic to offer great attractions to those members of the profession who wish to supplement their undergraduate studies while remaining in this country.

— The Swedish physician, Santesson, relates in *Hygiea* that he was called to a young man of twenty-five with an abscess in the left iliac region. Examining him M. Santesson found the right side of the scrotum empty, and in the left side a hard, round

body, of the size of a musket ball, covered by the skin, but no trace of cord or testicle. A linear cicatrix on each side of the median line made him suspect castration. On interrogating his patient he learned that the young man, when seventeen or eighteen years old, had obeyed the Scriptural direction, If your right eye offends you, pluck it out, and had, with a planing iron, made an incision in the skin of the scrotum, extracted the testicle, and cut the cord on both sides. Local applications of cold water arrested the hæmorrhage, and he recovered in about three weeks. Certainly it seemed to him disagreeable to live with an empty scrotum, and fearing that he would gain heaven later than he thought he decided upon a new operation. With the chisel he made an incision in the scrotum on the left side, and introduced into the wound a glass ball, which served as a testicle, and relieved his disagreeable void. The wound healed slowly. M. Santesson extracted the ball, and presented it to the Society of Medicine of Stockholm.

— Lecturers on First Aid to the Injured and kindred subjects, which have become so popular of late, do well to translate all technical terms which they may have occasion to use completely into the vernacular, otherwise they may be confronted at their examinations by such startling statements as this, which we learn from an English contemporary to have been actually rendered on such an occasion: "Bleeding from the nose is neither *Artillery* nor *Venus*, it is *Caterpillary*."

— Whatever may be said (and there is much) in favor of the requirement of some compensation from the beneficiaries of a hospital, it is worthy of remark that at Guy's, which for various reasons is a most conspicuous example of the inauguration of the commercial system, the motto of the founder was *dare quam accipere*. In view of the change of policy it would seem appropriate to make a slight change in this doctrine of the founder so that it should read *accipere quam dare*.

— A female child, aged six, who was brought to one of the London hospitals for ringworm was noticed to have a patch just above the middle of the forehead, where the skin was white, and the lock of hair growing from it was almost, if not quite, white. The mother had a precisely similar condition, and said that the lock had, at one time, been as long as the rest of her hair, but she had now cut it short. She also said that it was hereditary in her family, having occurred in two of her sisters and one brother, in her father and her grandfather, and that one of her sisters had four children similarly affected, all girls.

— French Fun: Dr. B., after having bought a lot in the Montparnasse Cemetery, went to the marble worker to order the tomb. After the details were arranged the marble worker said: "Monsieur did well to select this cemetery, it is so quiet; and then Monsieur le Docteur must know a good many people here."

— A writer in the *Lancet* describes the use of a Hodge pessary in the treatment of a fracture of the lower jaw at the symphysis with external wound of two inches in length. The desideratum was an apparatus which should immobilize the jaw and yet allow of the dressing of the wound. The pessary was bent so as to allow the chin to protrude through its ellipse, one bar being moulded so as to support the fracture anteriorly, the other from below. Tapes were sewn to the rounded ends of the pessary for securing it.

— Rev. Daniel Waldo, a graduate of Yale in 1788, who died in 1864 at the age of one hundred and two, gave as one of the rules of life which he had acted upon, and which he believed had enabled him to live so long, "Never allow yourself to fall into a fit of anger. One storm of angry passion will cut short your life more than an ordinary run of fever."

— A very unusual thermometric record for the "temperate" zone is announced from New South Wales. The unfortunate locality is the town of Bourke, some 500 miles from Sidney. It is situated on an immense plain at about the sea-level, separated from the coast by a chain of low mountains. The temperature, as published by the government meteorologist at Sidney, showed an average at the hottest period of the day for the first fifteen days of 1884 of 110.6° F. The lowest figure for any of the days was 103.5° F., and the highest 122° F., which was reached two days in succession.

MEDICO-LEGAL NOTE.

— The following is stated in the Maryland *Medical Journal* on the authority of Mr. Willoughby N. Smith of the Baltimore bar, and Lecturer on Medical Jurisprudence in the College of Physicians and Surgeons, as being the state of the law in the United States with respect to the sanctity of communications imparted in confidence to a physician by a patient: —

In the absence of any statutory provision to the contrary, it is well settled that a physician or surgeon may be *compelled* to disclose any communication made to him in professional confidence. — *Stephens' Digest of Evidence*, Art. 117.

The States which have enacted statutes changing this rule of the common law are the following: Wisconsin, New York, Michigan, Iowa, Minnesota, Missouri, Ohio, Indiana, and Nebraska.

The statute of Wisconsin provides that "no person duly authorized to practice physic or surgery shall be *compelled* to disclose any information which he may have acquired in attending any patient in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon." — *Wisconsin Revised Statutes*, Sect. 4075.

The statutes adopted in New York, Michigan, Minnesota, Missouri, Ohio, Indiana, and Nebraska, provide *either* that a "person duly authorized to practice physic or surgery" shall not be "competent" or that he shall not be "*allowed*" to make the disclosure. *But* by the statutes of Iowa, Indiana, and Minnesota such testimony "may be received with the consent of the patient" in all cases, and in Minnesota the prohibition, in the absence of such consent, is confined to civil cases: the "regular physician or surgeon" may be

compelled in that State in criminal cases to disclose communications reposed in him in confidence by a patient while in actual attendance upon the patient in the capacity of medical adviser.

Correspondence.

SOME SUGGESTIONS UPON CEREBRO-SPINAL MENINGITIS.

MR. EDITOR, — The paper upon Cerebro-Spinal Meningitis by Dr. Mason, in the JOURNAL of February 7th, was of special interest to me from the fact that the *first* and many of the succeeding cases that occurred during the epidemic mentioned by Dr. Sargent came under my care.

I will go no further than to give the treatment that was found the most successful, namely, to purge drastically with salts. If the purge was omitted over twenty-four hours the patient became unconscious, with a tendency to convulsions. As soon as the bowels were moved freely these symptoms disappeared.

In a case that occurred some months after the epidemic had apparently subsided a different mode of treatment was adopted in consequence of the disease having advanced to the convulsive stage.

A little girl, aged six years, vomited in the morning. I was called soon after. She could hardly be said to be sick, yet something in her appearance reminded me of my former cases. I cannot describe it better than by saying she did not seem to comprehend any question that was asked her. Yet her mother would not admit that this was unnatural, attributing it to my being a stranger.

On my visit the next morning this peculiarity was, I thought, more marked; still the mother would not admit that there was anything unnatural. Soon after my visit she became convulsed, and as I was not sent for, found her so on my visit at night. At this time her pulse was a mere tremor. My first effort was to stop the convulsions, as she would soon die for lack of respiration. As this was before the use of anæsthetics, my reliance was upon opium.

My principal object in giving the treatment in this case is to show that if a medicine is given which is adapted to control the symptoms for which it is given it can be pushed until the object is attained, without its ultimate effects being manifest.

To control the convulsions I dealt out three grains of sulphate of morphine in six powders. I inquired of the mother if she had any laudanum; she brought out a two-ounce vial full. Dr. Jewett, the prominent temperance lecturer, lived opposite, and kindly offered to take charge of the patient during the night; therefore I am confident the medicine was given as directed. My directions were to give one of the powders of morphine every half hour until it controlled the convulsions; if the morphine did not do it then follow it with a teaspoonful of laudanum every half hour. It will be remembered that this was for a child six years old.

On my visit early in the morning I found the child had taken all the morphine and all of the laudanum, yet had a slight tremor of the facial muscles; not a symptom of the ultimate effects of the drug could be discovered, no change in the respiration, no contraction of the pupils. She had no further manifestation of the disease, except the effect of the deposit of pus upon the membrane of the brain. She was as a new-born infant, and the change in her was as from infancy to childhood, having to learn everything anew.

HENRY G. DAVIS, M. D.

NEWTON, MASS.

Miscellany.

LIQUOR LICENSES IN BOSTON.

THE recent action of the Police Commissioners of Boston in increasing the price of the liquor licenses is supposed to be due in part to the influence of the Law and Order League, and undoubtedly is in accord with general public sentiment as reflected in the daily press. The amount to be collected for the liquor licenses is left within certain limits to the local board, the statute providing, for instance, that the innholder's license (first class) shall be not less than $100 nor more than $1000 per year. Under the former rules the amount was fixed at $300, but is now increased to $600. This schedule (A) applies to about thirty hotels in the city proper. Another schedule (B) has been established for hotels outside the old city limits, also numbering thirty, and its fee is $350. These licenses all convey the right to sell all kinds of liquors at all hours. The other classes of licenses, more or less restricted as to the kinds and amounts of liquor to be sold, are held by common victualers, brewers, grocers, etc., and have all, without exception, been increased in price, the increase varying generally from twenty-five to fifty per cent. Only the druggists' licenses, which are fixed by statute at $1, remain unchanged.

The extent of the change may perhaps be best realized when it is said that it is estimated that the income from licenses in the city during next year at the new rates will amount to $550,000, as against about $310,000 for the current year. This is supposing that the number of licenses remains as at present at about 2800.

POISONOUS WALL-PAPERS.

As the result of government inquiry, concerning foreign legislation or municipal enactment having for its object limitations, restrictions, or safeguards in the manufacture, use, or sale of arsenical and other poisonous colors in the tinting of wall-papers, textile fabrics, and other industrial decorative purposes, the *British Medical Journal* reports that the German Imperial law, which supersedes all local legislation, is by far the most complete, and has served as a basis for those of Denmark and other countries; the Austrian laws are very satisfactory, and probably would be more applicable to the circumstances of Great Britain. In accordance with a suggestion of the Board of Trade, further special inquiries have been made by her Majesty's representatives abroad on the subject of the customs regulations affecting the importation of textile fabrics and wall-papers, and the result of such inquiries has been to show that no special customs regulations or restrictions exist having for their object the detection of poisonous substances employed in coloring these articles imported into the undermentioned countries: Baden, Bavaria, Belgium, Denmark, France,

Germany, Greece, Netherlands, Portugal, Roumania, Saxony, Servia, Spain, Switzerland, United States, and Würtemberg. In Austria there are certain customs restrictions which will probably be made more stringent. In Italy the new customs tariff, approved by royal decree of August 9, 1883, enacts that goods which the competent authorities shall decide to be dangerous to the public health shall be destroyed or sent back at the cost of the importer. In Sweden and Russia elaborate instructions are in force.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 1, 1884.

Deaths reported 2509 (no reports from Cincinnati and Buffalo): under five years of age, 904: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 297, consumption 386, lung diseases 308, diphtheria and croup 57, diarrhœal diseases 43, scarlet fever 60, typhoid fever 32, measles 21, puerperal fever 19, malarial fevers 18, whooping-cough 14, erysipelas 14, small-pox four. From *typhoid fever*, New York eight, Chicago seven, Philadelphia six, Boston, New Orleans, and Lowell two each, Baltimore, St. Louis, District of Columbia, Pittsburg, and Providence one each. From *measles*, Baltimore seven, New Orleans five, New York and District of Columbia three each, Philadelphia, Lawrence, and Taunton one each. From *puerperal fever*, New York and Chicago three each, Brooklyn, Boston, St. Louis, and Milwaukee two each, District of Columbia, Lowell, Cambridge, New Bedford, and Chelsea one each. From *malarial fevers*, New York seven, New Orleans four, Brooklyn three, Chicago and St. Louis two each. From *whooping-cough*, New York four, Philadelphia, Boston, and Baltimore two each, Brooklyn, Chicago, St. Louis, and New Haven one each. From *erysipelas*, New York seven, Philadelphia and Brooklyn two each, Chicago, Boston, and Baltimore one each. From *small-pox*, New Orleans three, Philadelphia one.

In 71 cities and towns of Massachusetts, with an estimated population of 1,299,412 (estimated population of the State 1,955,104), the total death-rate for the week was 18.00 against 16.72 and 16.28 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending February 16th, the death-rate was 20.1. Deaths reported 3367: acute diseases of the respiratory organs (London) 334, whooping-cough 120, scarlet fever 79, measles 77, diarrhœal diseases 44, fever 40, diphtheria 39, small-pox (Sunderland 10, Birmingham three, London two, Liverpool one) 16. The death-rates ranged from 11.8 in Portsmouth to 25.8 in Sunderland; Leicester 16.5; Leeds 17.7; Birmingham 17.8; Blackburn 17.9; Bradford 19.4; London 19.8; Birkenhead 21.2; Sheffield 21.7; Manchester 22.8; Liverpool 24.9. In Edinburgh 18.2; Glasgow 25.4; Dublin 31.4.

For the week ending February 16th, in the Swiss towns, there were 40 deaths from consumption, lung diseases 35, diphtheria and croup 13, whooping-cough 10, diarrhœal diseases 10, scarlet fever four, typhoid fever two. The death-rates were, at Geneva 18.3; Zurich 23.6; Basle 20.2; Berne 23.3.

The meteorological record for the week ending March 1st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

OBITUARY.

DR. C. M. LORD, of Washington, one of the most respected and skillful physicians of the national capital, is dead. He resided for many years on Capitol Hill, and was well acquainted with most of the distinguished men of his time. His personal and social qualities gave him wide popularity. He was born in Troy in 1840, and graduated at the University of Pennsylvania. He was a surgeon in the Union Army and Navy during the war, and was for a time in charge at the Old Capitol Prison. For fourteen years he was surgeon at Providence Hospital.

CORRECTION FROM BALTIMORE.

MR. EDITOR, — Allow me to make a correction in my letter of the 28th ult., published in the JOURNAL for March 6th. Page 237, line 17 from bottom, should read "His opinion *is the more important*," instead of "*has the more weight*," as it was not the intention of your correspondent to attach the greater weight to Dr. Billings's opinion *because* it was *opposed* to that of Dr. Chancellor. I hope this may be corrected at once, lest it may give offense where none was intended. B.

BALTIMORE, *March* 8, 1884.

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MARCH 1, 1884, TO MARCH 7, 1884.

PERIN, GLOVER, lieutenant-colonel and surgeon, medical director, Department of Dakota. Leave of absence extended twenty days. S. O 23, headquarters Division of the Missouri, March 5, 1884.

BILL, J. H., major and surgeon. Granted leave of absence for one month. Paragraph 1, S. O. 20, headquarters Department of the Platte, March 3, 1884.

BAILY, J. C., major and surgeon. Granted leave of absence for one month, to take effect on or about March 1, 1884, with permission to apply to the Adjutant General of the Army, through division headquarters, for an extension of three months. S. O. 24, headquarters Department of Texas, February 26, 1884.

BACHE, DALLAS, major and surgeon. Leave of absence extended seven days. Paragraph 1, S. O. 43, headquarters Department of the East, March 5, 1884.

STEPHENSON, WILLIAM, first lieutenant and assistant surgeon. Ordered to Fort Niobrara, Neb., for temporary duty, on completion of which to return to his station, Fort Omaha, Neb. Paragraph 4, S. O. 20, headquarters Department of the Platte, March 3, 1884.

FISHER, WALTER W. R., first lieutenant and assistant surgeon. Assigned to duty at the Presidio of San Francisco, Cal., from 18th inst.

POLHEIMER, A. S., first lieutenant and assistant surgeon. Assigned to duty at Fort Winfield Scott, Cal., from 18th inst. S. O. 23, paragraphs 1 and 2, headquarters Department of California, February 21, 1884.

PHILLIPS, JOHN L., first lieutenant and assistant surgeon Assigned to temporary duty at Fort Warren, Mass. Paragraph 2, S. O. 39, headquarters Department of the East, February 28, 1884.

BENHAM, R. B., first lieutenant and assistant surgeon. Relieved from duty at Fort A. Lincoln, D. T., and ordered to Fort Sisseton, D. T., for duty. Paragraph 1, S. O. 22, headquarters Department of Dakota, February 26, 1884.

RHODE ISLAND MEDICAL SOCIETY. — A quarterly meeting of the Society will be held in Lyceum Hall, 62 Westminster Street, Providence, on Thursday, March 20, 1884, at ten A. M. Papers will be read by Dr. N. O'D. Parks on Topical Cardiac Blistering in the Treatment of Acute Rheumatism, and Dr. Herbert Terry on The Treatment of Puerperal Fever.

GEORGE D. HERSEY, *Secretary*.

ANNUAL MEETING OF THE SANITARY COUNCIL OF THE MISSISSIPPI VALLEY. — The sixth annual meeting of the Sanitary Council of the Mississippi Valley will be held in the city of Memphis, Tenn., on Friday, March 21, 1884, instead of Wednesday, the 19th, as previously announced.

DEATH. — Died, at Groveland, Mass., March 7, 1884, Morris Spofford, M. D., M. M. S. S., aged fifty-five years.

BOOKS AND PAMPHLETS RECEIVED. — House Drainage as Constructed by the Durham House Drainage Company of New York. By William Paul Gerhard, Chief Engineer Durham House Drainage Company. New York. 1884.

Proceedings of the Naval Medical Society. Vol. I. No. 6. Washington. 1884.

Fifty-Eighth Annual Report of the Massachusetts Charitable Eye and Ear Infirmary. For the Year 1883. Boston.

Rhode Island. Thirtieth Registration Report, 1882. Thirtieth Report upon the Births, Marriages, and Deaths in the State of Rhode Island for the Year ending December 31, 1882. Prepared by Charles H. Fisher, M. D., State Registrar of Vital Statistics, etc. Providence. 1883.

Circulars of Information of the Bureau of Education. No. 4. 1883. Recent School-Law Decisions. Compiled by Lyndon A. Smith, A. B., LL.D. Washington: Government Printing Office. 1883.

Study of a Case of Multiple Sarcomata of the Skin (Myeloma, Mycosis Fungoides, Mycosis Fongoide, Inflammatory Fungoid Neoplasm). By James Nevins Hyde, A. M., M. D., Professor of Skin and Venereal Diseases, Rush Medical College, Chicago. Read at the Fourth Annual Meeting of the American Dermatological Association, Newport, R. I., August 30, 1881. Printed by Oliver & Boyd. Edinburgh.

Original Articles.

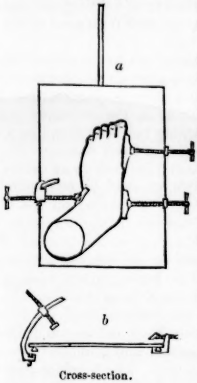
ON THE USE OF FORCE IN THE TREATMENT OF RESISTANT CLUB-FOOT.

BY E. H. BRADFORD, M. D.

It is certainly desirable to place in the hands of the general surgeon a method by which obstinate, relapsed, or half treated cases of congenital talipes equino-varus may be cured without the expenditure of a great amount of time or the trouble of a great amount of special detail. This is particularly needed in the service of a large general hospital, and in the work of a country practitioner. The operation of excision of the tarsus has probably come into vogue on account of this need; but although this mode of procedure is apparently attended by slight risk and followed by excellent results, if equally good results can be obtained by less severe surgical interference the method is certainly to be discarded. Personal experience [1] in tarsotomy has led me to this conclusion, for although excellent results were obtained it appeared that the resistance to correction was not due so much to the deformity of the tarsal bones as to the tissues (presumably ligamentous) binding the displaced bones together, and that theoretically it was better surgery to attack the latter than the former structures. Simple tenotomy is not sufficient to divide the ligaments which lie close to the tarsal bones. A direct incision, proposed and successfully carried out by Dr. Phelps, of Chateaugay, is objectionable on the ground that correction would leave a gaping wound, and also because on general principles a deep incision is to be avoided if equally good results can be obtained without. Gradual stretching, the method most in vogue, demands in the most obstinate cases a great deal of time and a daily attention not always at command.

The method of forcibly rectifying a club-foot is not a new one, but it has not found favor because of the mechanical difficulties encountered, and also because a practicable means of fixation after such correction had not been in use, consequently not enough has been gained to sanction the procedure. Furthermore, tradition has deterred many surgeons from immediate correction in the fear of subsequent non-union of tendons.

The first mechanical means of value for the purpose of immediately correcting obstinate club-foot was reported by Dr. Morton, of Philadelphia. In two cases in which I had the opportunity of testing this method its efficiency was proved, and fair results obtained; perfect success was not gained from the fact that perfect fixation through lack of experience in the method and in the mode of after-treatment was not effected. The appliance seemed to be defective in that it lacked precision, relying as it did for the correcting force upon straps, which are liable to stretch and slip. The accompanying drawing (Fig. 1) illustrates an appliance which appeared to remedy this difficulty.



The object of the appliance is to exert pressure under control of the operator in three directions, and also to enable him to twist and raise the front of the foot.

The apparatus consists: —

(1.) Of a plate large enough for any foot.

(2.) Of three steel buffers or padded plates which are attached at the ends to steel screw rods, playing through sockets with a female screw thread at the sides of the large plate. By turning the screws, which is done by the handles, the plates or buffers are pushed forward. They should be placed so as to press (1) upon the side of the first metatarsal; (2) on the side of the os calcis just beneath the inner malleolus; (3) on the outer side of the foot over the projecting head of the astragalus. The female screw through which the male screw plays is adjustable upon an arm curved so that pressure can be applied when it may be found necessary.

Fig. 1.

Cross-section.

The sockets and arms are arranged so that they can be shifted and placed at any point along the side of the large plate, or can be shifted from side to side, so that the appliance can be used for either foot.

(3.) A straight rod, extended in the plane of the plate, gives increased power in raising the front of the foot. This is not always needed, and can be removed.

In operating upon obstinate cases of club-foot (the only cases for which this method is designed) the method of procedure is as follows: Tenotomy is performed in the usual way, the plantar fascia divided first, the tibiales tendons (if contraction is present) and the tendo Achillis last (after the deformity at the arch of the foot has been in a degree corrected); the foot is then forcibly manipulated with the hands, pressure being exercised upon the projecting head of the astragalus by the thumbs, and force applied in a counter direction by the hands grasping the ankle and fore part of the foot. It will be found in certain cases that complete correction of the deformity cannot be accomplished by the hands alone, and the hindrance will be seen to be not a shortened tendon or any tissue accessible to the tenotome.

The instrument just described is then to be applied, and the screws turned and adjusted so that the plates will press upon the os calcis, the head of the astragalus, and the side of the first metatarsal as far as its articulation with the tarsus. The foot will now be firmly held, and by additional turns of the screw force can be applied in the desired directions. Rotation upwards and outwards can be effected by twisting the plate and the equinus deformity of the foot can be corrected by pressing the end of the plate upward. In case it is desired to increase the power in this direction this can be done by increasing the length of the handle. If the screw plates are properly adjusted it will be found that there is no danger of a fracture, as the pressure can be so directed that the ligaments will yield before any of the bones of the tarsus can be broken. An anæsthetic is of course required, and correction will be done gradually rather than by any sudden tear. The extent to which force can with safety be applied is with difficulty defined; it may be said, however, that experience shows that a much greater pressure can be used than would at first be thought feasible, — in a majority of cases enough force can be used to convert the foot from the position of varus to that of valgus, and to correct the

[1] Boston Medical and Surgical Journal, 1881, p. 241.

equinus position. In the simpler cases this is always possible; in the severer cases some minutes should be given to gradually stretch the foot. Sometimes complete correction is not possible at one sitting, and something will have to be left for after treatment or for a second sitting.

After the foot has been brought into a position which is nearly normal, and the contracted tissues so stretched that the foot can be held without a great amount of force, the foot should be fixed in the corrected position. For this purpose nothing has been found so useful or comfortable as a plaster-of-Paris bandage properly applied. The foot should be held in as nearly a normal position as is possible, grasped by one hand at the toes while counter-pressure is exerted on the leg. Roller plaster bandages prepared in the way that is customary for plaster jackets are wound around the foot and leg which are first to be covered with one layer of sheet wadding. The bandages are to be applied without loosening the hold upon the foot, which is to be kept in the corrected position until the bandages have become sufficiently hard, not to yield when the hold on the foot is loosened, and additional turns are then applied around the toes. The bandage should be carried above the knee and half way up the thigh, and the leg should be flexed at the knee thus preventing any subsequent rolling of the limb within the plaster bandage. After the dressing has become stiff, and before it is absolutely hard, it can be cut through by two cuts along the dorsum of the leg and foot and cross cuts over the foot and thigh so that the lid of the plaster box may be lifted and the parts inspected subsequently when necessary without destroying the bandage.

There should be no wrinkles in the bandage, and no pressure should be made upon the dorsum of the foot while the gypsum dressing is hardening. After ten days or three weeks the stiff bandage may be removed, and if the foot is sufficiently corrected a walking shoe applied.[1]

The chief objection which will be urged against this method will be the supposed risk incurred. It would seem, however, that the danger is not so great as would be thought. Experience with osteoclasis has proved conclusively that the temporary pressure upon the skin necessary to break bone does not cause sloughing or even an abrasion; the same is true of the pressure required to rectify a club-foot. Experience has also proved that it is safe to fix a limb immediately after osteoclasis with plaster-of-Paris bandage. The same appears to be the case in club-foot, if ordinary care is used in applying the bandages. Sloughs may occur on the inside of the ball of the toe, on the outer and under side of the sole, and on the dorsum of the foot; but these sloughs are not more troublesome than those sometimes occurring in the use of Scarpa's shoe or appliances, held by straps, and they are not so liable to occur from the fact that in a foot held in a well-applied plaster-of-Paris bandage the pressure is not confined to a few points, but is nearly uniform over the whole foot. In case a slough appears (a fact to be determined by lifting the lid of the plaster-of-Paris box which holds the foot), the following appliance (Fig. 2) can be used

FIG. 2.

until the skin has recovered so that a plaster bandage can again be reapplied if a second one is necessary.

A plaster bandage is applied in the ordinary way from the lower part of the leg above the malleoli to above the knee, which should be bent; a strip of strong iron rod is placed on the first layer of the bandage, bent at the top so as to half encircle the thigh, to pass along the outer side of the leg, and to project slightly above and to the outer side of the outer edge of the foot. At the lower end of this rod a buckle is attached, and the portion lying upon the plaster bandage is thoroughly incorporated by the successive turns of the bandage. A strip of rubber adhesive plaster is wound around the foot (which can be protected in the sole by card-board if necessary), and to the free end of the plaster at the level of the terminal end of the fifth metacarpal a piece of webbing is sewn. This is to be buckled to the buckle attached to the iron rod. Other strips of webbing and other buckles can, if needed be put at any desired point, and by a wrench the iron can be bent in any direction, so that the point from which the pull is to proceed can be placed at any desired direction; additional strips of iron rod can also, when necessary, be applied. It is of course desirable to prevent the whole appliance from slipping down, and this can be done by placing a long strip of adhesive plaster on the skin of the leg before the gypsum bandage is applied, and a buckle on the outside of the bandage; if the free end of the plaster is secured in the buckle, slipping of the appliance down is prevented. A stocking and slipper can be worn on the foot if a hole is cut in the side for the strip of webbing to pass through, and the patient can bear weight upon the foot.

As an objection to the method of applying a fixed dressing, it has been said that the plaster dressing being a fixed one and not allowing motion, gradual gain cannot be made beyond the position in which the foot has been placed. This is of course true, but almost complete correction can be gained in a majority of cases immediately, and the further gradual gain is only such as can be secured by a walking shoe. A fixed dressing secures the indicated rest after the force required to gain the correction, and enables the stretched tissues to adapt themselves to the new position. The foot is forcibly put in a new position, and may be said to have suffered a "sprain," the indications for the treatment of which are fixation, which is most readily secured by a plaster bandage.

The danger of non-union of tendons after correction immediately following tenotomy in resistant cases can practically be disregarded, although it is mentioned by many authorities. In this, as in many other particulars, experience appears to disprove tradition.

After complete correction, — and by that term is meant that the plane of the sole of the foot can be brought to a right angle with the axis of the leg, and that the line of the inner edge of the foot turns to the outside of the plane of the inner edge of the leg, — and after all pain and swelling have subsided, a "walking" shoe is applied. This is to be worn until the muscles have recovered the usual balance of power, the object being to prevent the possibility of incorrect walking.

The requisites of a "walking shoe" are that it should be easily applied, without the supervision of the surgeon or a skilled nurse, that it should allow motion in all directions except those toward the position of former distortion, and that it should not be cumbersome,

[1] Hahn. Berl. klin. Woch., March 19, 1883, describes a new method of holding the foot while a plaster bandage is applied.

heavy, or unsightly, and that it can be readily worn for some time. Various appliances have been in use for this purpose; but the one which has seemed to me the most efficient is the varus shoe, which Dr. C. F. Taylor, of New York, has devised and used, and for an explanation of which I am indebted to him. A published description of this useful appliance had best be left to the originator.

TABLE OF CASES OF CONGENITAL CLUB-FOOT TREATED BY THE USE OF FORCIBLE STRAIGHTENING.

No.	Name.	Address.	Age.	Deformity.	No. of Operations.	Hospital.	Result

16	Joseph Mahoney.	Longwood.	4 "	Double.	2	Children's Hospital.	Imperfect.
15	X Y	Dorchester.	7 "	Double.	3	Children's Hospital.	Imperfect.

All of the foregoing cases were of the congenital deformity of an aggravated type; those of acquired variety were not included in the list.

By a *perfect* result is meant that the patient stands and walks on the whole of the sole of the foot; can when standing on the heel flex the front of the foot above the floor, and that the patient's foot presents no projection of the head of the astragalus or any of the tarsal bones on the outer and upper surface of the foot.

By an imperfect result is meant a condition of the foot falling short of this standard. By nearly perfect, is meant that the heel can be brought to the floor without twisting the foot, but that the front of the foot cannot be raised without lifting the heel. This is true of the left foot in Cases VIII.–XI. The patients are still under treatment.

Nos. 9, 10, 11 were treated by forcible manual straightening without mechanical assistance. Nos. 14, 15, 16 were experimental cases in a measure; they were the first ones treated in this way, and were but partly successful for the reason that the method was not perfected, and chiefly because the feet were not fixed after operation from fear of injury following the use of plaster-of-Paris bandages, and because the bandages were not applied above the knee with the limb bent, and twisting in of the foot inside of the bandages occurred. The deformities were not more resistant and were less severe than in the other children who were successfully treated. They were all benefited, and walk with slight noticeable deformity except when the feet are bared. Case XVI. is instructive from the fact that an aneurism of the posterior tibial followed a month after tenotomy. The tenotomy was freer than was needed, but at the time it was thought advisable to cut very freely as the appliance for stretching was not perfected. The aneurism was, a month later, cut down on, and found to proceed from a pin-hole opening in the artery. This was tied as any bleeding point would be, and the patient recovered promptly, and at present, three years later, walks without appliances. An equinus deformity remains, the patient being unable to bring the heel to within one inch of the ground with twisting the front of the foot, and walks on three fourths of the sole.

Case I. has been the longest under observation, and would indicate that there is little danger of recurrence of the deformity. At the present time he walks perfectly well, without appliance, and with perfect feet. For a year and a half after his discharge from the hospital he has been seen professionally but five times. He wore for a year light walking supports, which his mother has been able to adjust herself without medical supervision.

Case II. has not been seen since his discharge from the hospital. Letters from the parents report that at

August 10, 1882. October 4, 1882.

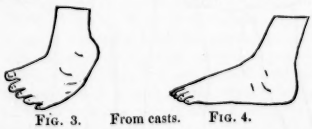

FIG. 3. From casts. FIG. 4.

the present time, eighteen months after discharge, the child is walking perfectly.

The same is true of Case III.

Case IV. was one of equally severe deformity. The patient is now, eight months after discharge, able to walk perfectly. The amount of flexibility at the ankle-joint is indicated by the accompanying tracing (Fig. 5),

taken by placing a piece of paper at the side of the leg, the sole of the foot being flat on the floor.

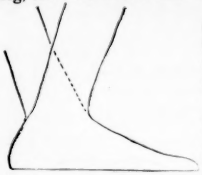

FIG. 5.

In Case VI. the patient suffered a good deal of pain for a week, and on the removal of the plaster a slough was found on the side of the ball of the toe and also on the dorsum of the foot. The appliance as indicated in Figure 2 was used, and the patient went about with crutches. He began to use a walking shoe in six weeks, and was discharged from the hospital, and three months later was in the position indicated in the photograph, and able to walk about

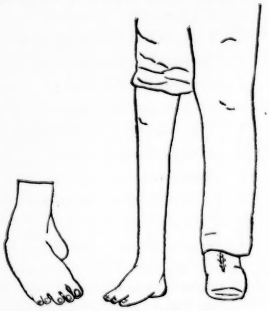

FIG. 6. Drawn from cast. August, 1883.

FIG. 7. From photograph. January 1, 1884.

FIG 8. From imprint of sole of foot. — January 1, 1884.

freely without appliance, crutch, or cane, having taken care of his foot himself during that time, he being seen medically but six times, chiefly for observation. The treatment was perhaps hurried unnecessarily, and an earlier removal of the plaster would have prevented the sloughs appearing. These, however, did not in any way prevent the continuance of treatment.

The patient's foot was very resistant, and at the time of operation all possible force was required after tenotomy to press it into a normal position. The patient was fifteen years old, and had been walking on a deformed foot all his life.

Case VIII. was the most resistant of the series, partly because the foot was small and force was therefore with difficulty applied. Three sittings were necessary to straighten the left foot; a small slough appeared, and the spur appliance was used. The right foot was straightened in one sitting.

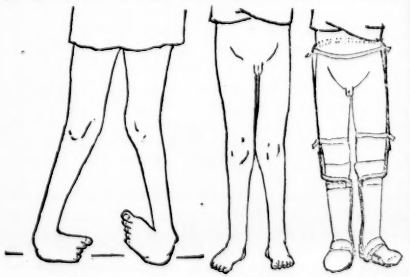

FIG. 9. From photograph. September, 1883.

FIG. 10. From photograph. January 1, 1884.

FIG. 11. From photograph. January 1, 1884. Wearing appliance.

The length of time required in the treatment of the above cases varied. In the cases where the feet were the least resistant the plaster bandage was removed in from three to four weeks, and walking shoes applied immediately. In Cases II., V., and XIII., the whole active treatment occupied but a month, after which time the patients were left to the parents' care and not seen by the physician, although directed to wear the walking shoes for a year. Case XIII. was seen a year afterwards, and the feet found to be in a perfectly satisfactory condition. The same may be said of Case V., seen three months after discharge from the hospital. Where greater resistance was encountered, longer time was needed; Case VI. was seven weeks under active treatment. Case VIII., the most resistant of the cases collected, was four months under constant observation. In both the plaster bandages were removed on account of sloughs, and the spur appliance used until the feet were in a condition for a walking shoe.

It should be born in mind that the method of treatment by extreme mechanical force is not to be used except in extreme cases, and in cases where a speedy result is desirable. It is not claimed that equally good results cannot be obtained by other more gradual methods. The writer, however, believes the method to be safe, to save time and trouble, to give perfect results.

A CASE OF "WASTING PALSY" (PARTIAL).[1]

BY GEORGE M. READ, M. D., DORCHESTER.

MR. A., American, married, merchant, aged fifty-two years, five feet ten inches high, ordinary weight 160 pounds, gave a good family history, and said of himself that, aside from occasional slight attacks of "indigestion," he had always been well till within a year. For thirty years business had confined him closely, and he had been on his feet almost constantly during the day, standing much of the time at his desk. Less than a year previous to first consulting me (February 5, 1883) Mr. A. thought his left lower limb showed fatigue more readily than usual, and found it necessary to *sit* at his desk. Later an ordinary walk became fatiguing, and he was aware of sensations of "coolness," and "prickling" in the weak member, with occasional muscular "twitchings" as the limb became tired. Within a month the patient had thought the left extremity smaller than its fellow, and in consequence sought medical advice. There has been slight œdema of left foot. Mr. A. has never had a chancre nor suffered a blow or fall at any time. Special senses and sexual function unimpaired; appetite poor; bowels constipated; micturition natural.

Weight at time of first interview 145 pounds. Inspection showed a man of tolerable muscular development, but with a small amount of subcutaneous fat. The left lower extremity was noticeably smaller than the right. No external signs of syphilis. Physical examination revealed nothing abnormal about heart or lungs. Pulse 76; temperature normal; tongue furred; breath offensive; stomach and intestines slightly distended by gas. No tenderness on pressure over any portion of the

[1] Essay by William Roberts, M. D., London, 1858.

spinal tract. Left upper extremity somewhat better developed than right, but patient is left handed. By measurement the left lower extremity was found smaller in circumference by five centimetres than the right, the comparison being between several points both above and below the knee. Muscles of nates apparently unaffected. Left foot slightly œdematous. Patient stepped from chair, stood, and walked well with his eyes shut. The cutaneous sensibility on the affected side seemed a bit increased. Use of the induced current proved the muscular contractility unimpaired.

Urine normal in amount for twenty-four hours; light colored; specific gravity 1025; neither sugar, albumen, nor casts.

Here is a case in which the only prominent symptoms are diminution in size and loss of power in one lower extremity, the functions of which, aside from this loss of power, are unaffected. In forming a diagnosis the history allows one to eliminate palsy from lead and atrophy resulting from continued rest or following injury to a nerve. One at first thought might confound this with a case of tabes dorsalis, but here the power of muscular coördination is unimpaired; the trouble is confined to *one* lower extremity, the cutaneous and muscular sensibility is undiminished, no history of pain or bladder affection, and the diminution in size of limb has followed closely the loss of power, the only other prominent symptom in this case.

It is seldom that "wasting palsy" attacks primarily and exclusively the muscles of the lower extremities. In a tabulated report of fifty cases of (partial) progressive muscular atrophy in but six did the disease make its appearance in the muscles of the lower extremities. Granting the diagnosis correct, we have here an unusual form of a comparatively rare disease.

The subsequent history of this case, covering eight months of treatment, is as follows:—

Mr. A. underwent, at the hands of a competent attendant, a thorough course of massage and galvanism, enjoyed daily surf bathing during the three summer months, lived as entirely in the open air as weather permitted, and confined his exercise within the point of fatigue. His diet consisted of easily-digested meat, strong beef soups, fruit, and plenty of milk and cream, a glass of sherry daily. Internal medication, small and increasing doses of sol. potass. arsenitis.

At our last interview (September 20th) Mr. A. showed a marked improvement in his general condition; tongue clean, appetite good with fair power of digestion. Has gained seven pounds in weight. Uses cane less, and is able to walk one or two miles without fatigue. The sensations of coolness and twitching of muscles is less. The puffiness of left foot is gone, and actual measurement shows a present difference in the circumference of the two limbs of but three centimetres +.

After eight months' observation, with the assurance that the disease has not progressed, but, on the other hand, shows a tendency toward amendment, a prognosis of permanent arrest with possible recovery seems not out of place.

The patient is advised to continue the treatment by massage and galvanism, live in the open air, and exercise with discretion.

Of eighty reported cases where the result is mentioned fifty per cent. have terminated in arrest, amendment, or recovery. Other general conclusions drawn from these cases are that the disease has its primary seat in the muscles, nerve changes following later when the muscular fibres have to a large extent disappeared.

Under the microscope "the striped elementary primitive fibres were found to be completely destroyed, the sarcous element being diffused and, in many places, converted into oil globules and granular matter, whilst the sarcolemma or tissue of the elementary fibre was broken down and destroyed."[1]

"Inherited proclivity," syphilis, exposure to cold, and muscular exertion are supposed to play a part in the ætiology of wasting palsy, though many cases occur in which none of these conditions have been present. A disease of adult life, more prone to attack males than females, showing a marked preference for the muscles of the upper extremities. The never-absent phenomena are "destruction of the muscular substance with consequent loss of power."

The treatment giving the best results is that generally recommended in the case reported.

PLASTER SUPPORTS.

BY W. T. BROWNE, M. D. (HARV.), JEWETT CITY, CONN.

THE object is to produce fixation with a material which shall be easy of application and easy of removal, being cleanly, light, durable, cheap, and ready for use as soon as one is done applying it. This may be attained by the use of plaster of Paris in the following way, for a support of the spine for instance: —

Take three, four, or five pieces of plaster gauze as wide as the support is to be, and long enough to go around the body and lap ten or fifteen centimetres each way. Lay these on another piece of the same length and eight or ten centimetres wider, and stitch them all together in the middle of their length, so that the seam shall extend up and down the front of the completed support; rub cosmoline into this seam in as narrow a line as possible. Hold the layers of gauze up to the body, so that the seam shall come over the sternum and the widest layer next the body, and cut out where they come under the arms and in the groins. It is not necessary to be very particular about the cutting, as the edge can be easily turned over the required amount after the plaster has been applied and before it has set.

The patient, having on the usual thin undershirt that fits well, and without any pads, is suspended in the usual way.

Eight hundred or one thousand grammes of plaster are now mixed with water to the consistency of cream, and while an assistant holds the gauze up to the body, the first layer is brought down smoothly and rubbed with plaster, then the next, and so on till all have been laid and filled with plaster; then turn the edges of the widest layer over the others, thus forming a binding and a smooth edge.

The plaster may be put on with a brush or with the hand; I prefer the hand. It requires about fifteen minutes to apply the plaster, so it should not set quicker than that.

Such a support is cleanly, for the edges being bound are not liable to crumble.

It is much lighter than when put on with rollers, as

[1] Meryon, Med.-Chir. Trans., vol. xxxv., p. 76.

it does not need to be as thick owing to plaster all being mixed at once and setting in a uniform mass.

A bandage made in this way is two or three millimetres thick in front, and four or five behind, and will last three or four weeks. If it is wanted to last longer, it may have more gauze and more plaster.

The cost of material is only a few cents, and the plaster will be found to be very thoroughly set by the time the binding has been turned and the surface rubbed smooth.

The plaster should be tested before using to ascertain how long it requires to set, and if it requires a few minutes more than by experience it is found to take to apply, it may be mixed a few minutes before required for use.

When it is necessary to remove the support it may be ripped open along the seam as readily as any seam in cloth.

It requires less experience to apply a bandage in this way, as it is impossible to draw it tighter in one place than another and produce ridges on the inside.

REPORT ON THEORY AND PRACTICE OF MEDICINE.[1]

BY GEORGE B. SHATTUCK, M. D.,
Visiting Physician Boston City Hospital.

I. ARTIFICIAL INFLATION OF THE COLON WITH GAS FOR DIAGNOSTIC AND THERAPEUTIC PURPOSES.

PROFESSOR V. ZIEMSSEN [2] has extended to the large intestine a procedure which he, and others, had previously advocated and practiced upon the stomach, namely, its artificial inflation with gas. Others, as well as himself, have undoubtedly advanced the suggestion of this wider application, but he seems to be the first to publish the results of its practical use.

The procedure is simple. A rectal tube six inches long is inserted and attached to rubber tubing terminating in a funnel, by which solutions of bicarbonate of soda and tartaric acid are successively introduced into the colon, for the extreme expansion of which about five drachms of bicarbonate of soda and four and a half drachms of the acid, giving off about five quarts in volume of gas, are required. To avoid the pain attendant upon a too sudden expansion of the wall of the intestine a divided introduction, with a few minutes' pause between each portion, of such an amount of alkali and acid is advised, each divided portion of solution being followed by a small quantity of water to prevent the evolution of gas in the tube. The escape of gas by the rectum is easily prevented by pressing the buttocks together. A lesser volume of gas is required when the object is merely to excite peristaltic action than for diagnostic purposes. In determining the diagnosis of transposed viscera, however, a smaller volume of gas is exceptionally recommended.

As an aid to diagnosis the procedure may be expected to throw light upon the position, the form, and elasticity of the colon; upon the resistance of the cæcal valves to the passage of gas; upon the communication of the colon or rectum with neighboring organs (the stomach, the small intestine, or the bladder); upon the position of contractions or closure of the intestinal calibre; and, under some circumstances, upon the nature of an impediment to the movement of fæces. From the therapeutic stand-point this method of gas-inflation is of value, and much superior to inflation by water, when one desires to excite strong peristaltic action; to tear through or dilate strictures; to reduce dislocations or intussusceptions; to separate adhesions.

Among other displacements of the colon V. Ziemssen has found the method useful in determining downward displacements, the relation of the intestine to ovarian and other abdominal tumors, and its interposition between the upper surface of the liver and the abdominal wall.

Typhoid fever and tuberculosis of the intestine are the only conditions mentioned as contra-indicating the use of the method. Neither in the presence of cancerous growths or fæcal accumulations, or of peritonitis with or without adhesions, have any untoward results occurred. The normal intestine will resist an enormous degree of inflation, as was proved by experiments upon bodies immediately after death, it having been found impossible to rupture the colon by such experiments.

II. THE RENAL CIRCULATION DURING FEVER.

A series of experiments upon dogs, in whom fever had been artificially induced, was undertaken by Dr. Walter Mendelson at the Pathological Institute of the Leipzig University, to ascertain the actual condition of the circulation in the kidney during fever. To his report [3] of this research the Cartwright Prize Essay for 1883 was awarded.

An instrument invented by Ray and named the oncometer, or bulk-measurer, was used to determine the condition of the circulation in the kidney, to which it can be readily applied without interfering with the functions of the organ. The dogs used were previously rendered immobile and insensitive for the application of the oncometer by brain puncture, and the pyrexia was produced by subcutaneous injections of pepsin, which was found to be the most satisfactory pyrogenous agent.

By these experiments it was determined that attendant upon the febrile process there is a diminution in the volume of the kidney; it was further ascertained by other experiments that this diminution, as was to be anticipated, was dependent upon contraction of the blood-vessels of the kidney; and again, by causing a local fever in the brain, whilst the kidney and the rest of the body remained of normal temperature, the conclusion was drawn that this contraction of the vessels was in all probability the result of a stimulus conveyed to them from the central nervous system, the stimulus being the consequence of irritation of the central vasomotor centres by the abnormally hot blood circulating through them during fever.

It is suggested that these conclusions, if correct, — and the experiments and their interpretation seem to have been quite carefully guarded — offer, in addition to the increased loss of water by the lungs and skin, another available explanation for the decrease in the amount of urine secreted by fever patients; and that the occurrence of albuminuria, a very constant symptom in nearly all high fevers, becomes readily understood in view of the extreme anæmia thus shown to affect the kidney during a hyperpyrexia, the glomerulal epithelium being insufficiently nourished with arterial blood and thus losing its function of retaining within

[1] Concluded from page 253.
[2] Deutsches Archiv f. klin. Medicin., vol. xxxiii., p. 235, 1883.
[3] Am. Journ. Med. Sci., October, 1883, page 380.

the vessels the albuminous portion of the blood plasma.

III. ABSCESSES OF THE LIVER.

The largest field for experience in the diagnosis and treatment of hepatic abscesses is found in tropical or subtropical countries, and we are glad to record the observations and conclusions of observers in such climates.

Quejia [1] confirms the common experience that abscesses of the liver are situated most often in the right lobe, and in the posterior border of this lobe especially. Abscesses of the superior surfaces of the liver are marked by severe pain of the right shoulder, while those on the concave or inferior surface give rise to disturbances of the digestive functions. Those large abscesses which occupy a considerable part of the thickness of the organ are accompanied by both symptoms, pain in the shoulder and digestive disturbances. Bearing in mind the frequency of abscess on the posterior border, and the tendency to open spontaneously into the bronchi, careful percussion, marking the limit of dullness, may afford a guide as to where incision should be made. The coexistence of pain in the shoulder and digestive perturbation, without dullness of astained form, but with the presence of the well-known symptoms of abscess, authorizes us in making an incision, directing it towards the centre of the organ. As to whether hepatic abscess is susceptible of spontaneous cure he quotes a case in which he found on post mortem an osteo-calcareous mass, due apparently to a hepatic abscess cured by cretification of its walls. In true hepatic abscess jaundice is always wanting. Incision should be practiced when the line of dullness reaches or passes the nipple, and in many cases is best made behind the nipple line.

IV. CAPILLARY PULSE.

As is well known, under normal conditions the flow of blood, which is intermittent in the arteries, becomes apparently continuous in the capillaries, but a physiological capillary pulse can be felt and seen under favorable circumstances in certain positions, as the end of the fingers when pressure is applied, the skin of the forehead, the inside of the lip, the fundus of the eye. Under some abnormal circumstances the capillary pulse becomes very apparent and nearly constant, especially in compensated aortic regurgitation attended by hypertrophy and dilatation of the heart, and diminution of elasticity of the arteries. Under such circumstances the aortic lesion is said to have been diagnosticated from observation merely of the capillary pulsations in the red mark on the forehead after removal of the hat.

Such a diagnosis should rather be designated a clever guess, for the capillary pulse is not confined to aortic regurgitation, but has been observed in cases of interstitial nephritis with arterio-sclerosis, of arterial atheroma, of chlorosis, of extreme anæmia, typhoid fever with hyperpyrexia, general paralysis, etc., etc.; many cases of aortic regurgitation, moreover, do not exhibit the phenomenon at all.

Ruault [2] advances the opinion that the capillary pulse can only occur when the elasticity of the capillaries is diminished, which is probably a sufficiently good explanation for its presence in aortic regurgitation, but not in typhoid fever and anæmias.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

March 10, 1884. The President, Dr. Charles D. Homans, in the chair.

SUPPRESSION OF URINE TREATED WITH CANTHARIDES.

Dr. W. C. B. Fifield reported the case, which he had seen in consultation with Dr. Rogers, of Dorchester. The patient was a hard drinker, whose symptoms were at first obscure, but who had later had albuminuria with casts. Complete suppression had lasted some days. Active treatment had been of no avail, and the patient was comatose and failing. Tincture of cantharides was then given hourly in drop doses, and after some hours the secretion was reëstablished, and the patient recovered so far as to be out.

TREATMENT OF BLOOD-POISONING FOLLOWING SURGICAL OPERATIONS.

Dr. W. G. Wheeler reported three cases, the publication of which is reserved. He asked the opinion of the Society as to the effect of large doses of quinine. It appeared to him that an irritable stomach is one of the early symptoms of septicæmia. He had not obtained the benefit from fifteen-grain doses that we read of, and it disagrees with the patient.

Dr. C. B. Porter agreed cordially with the writer in the importance which he placed upon drainage. He thought that the first cardinal principle in the treatment of wounds was that they should be properly drained, and second to that that they should be antiseptic. He had never seen any benefit from quinine given to reduce temperature in septicæmia, but relied entirely upon alcohol. So long as the patient is not intoxicated he is not getting too much. A rapid pulse is only an indication for more alcohol, and it is his rule to give it as soon as the temperature goes up. He has given as much as forty-eight ounces of brandy in twenty-four hours, with the results of lessening the fever. If it cannot be retained by the mouth it may be by the rectum, and if it cannot be held there alone it may be by the addition of morphia or chloral, which are in these cases of comfort to the patient. The essentials of treatment were drainage, disinfectants, and alcohol. He did not apply his remarks on quinine to the high temperature of typhoid. With reference to one of Dr. Wheeler's cases of slight abrasion, he said that he had seen blood-poisoning which had its point of departure in the granulations about a urethral calculus, which was got away at the second attempt to grasp it with the forceps, they being introduced into the urethra but once.

Dr. Wheeler spoke of the value of giving stimulant subcutaneously when it can be retained in no other way.

Dr. George W. Gay said that it would be an interesting point to determine the relative frequency of

traumatic fever, septicæmia, and erysipelas in cases of wounds both in hospital and in private practice. He thought a much larger proportion of patients having open wounds were thus affected than was commonly supposed. He had seen as much erysipelas outside the hospital as in it in proportion to the number of his cases. When it is prevalent in the hospitals it also prevails outside, and in the practice of men who have no hospital appointment. He is inclined to refer it oftentimes to some influence in the air rather than to any local cause. The speaker called attention to the fact that with patients who, after an operation or an injury, have a sharp attack of traumatic fever, and after seven to ten days recover from it, then for a certain time one may do almost any operation without much danger from septicæmia or traumatic fever. He was not prepared to say that a tentative operation was almost justifiable, but it does protect for a time. If, when the temperature begins to go up after operation, the surgeon looks for a blush and for pent-up pus he will find one or the other in a majority of cases. He had seen little or no good result from the use of quinine in cases of blood-poisoning. He also thought that another once much-praised drug, tincture of chloride of iron, is of no value in septic inflammation. He relied on drainage and antiseptics externally, and on opium, food, and stimulants internally.

DR. FIFIELD said that when the first report of the Boston City Hospital was issued it caused much comment on the mischief rising from placing a hospital on made land, but with every improvement in drainage and in cleanliness, as well as with Listerism, results have improved till they are now something to be proud of. Messrs. Callender, Keith, and Tate have shown conclusively that cleanliness is necessary to their success. The speaker could not reconcile these facts with a belief in atmospheric influences as a cause of the disease. Dr. Fifield could not too strongly express his belief in the value of stimulants in septic fever, or in any other, if the temperature became high. He had not seen any good produced by large doses of quinine, and he had a poor opinion of morphia, which he thought depressed patients who might bear the tincture of opium well. He thought that calomel was not sufficiently appreciated. With rising pulse and temperature, which are not controlled by opium, stimulants, and quinine, the use of ten to fifteen grains of calomel may empty the bowel, and relieve the fever. In proof of this he related two obstetric cases.

DR. PORTER said that it was particularly pleasing to find such unanimity of opinion as to the value of alcohol.

In surgical cases constipation sends up the temperature, and a purge brings it down. Menstruation also sends it up, so that he has the presence of the catamenia expressed on his hospital temperature charts. During its presence a rise of two or three degrees does not disturb him. We know very little as yet of the normal changes of temperature in health.

DR. FIFIELD had observed the same thing. He also referred to a recent article on the possibility of cutting short typhoid with calomel, and to the former belief that it could be cured with large doses of calomel and ipecac.

DR. GAY also agreed with Dr. Porter on the effect of the catamenia on temperature. He remarked that he had seen perhaps a half dozen cases of operations, involving large blood-vessels, which have done badly for ten or twelve days, when there has been a large secondary hæmorrhage, after which they have begun to recover. If this meant anything it meant that the old plan of bleeding was sometimes a good one. Our ancestors, with their emetics, cathartics, and bleedings, may not have been so far wrong as has since been supposed.

DR. FIFIELD reported a case of purpura in which there were unsuccessful attempts to check hæmorrhage. Contrary to expectation the bleeding seemed to benefit the patient. Bleeding was the treatment of the ancients.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.[1]

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M. D., SECRETARY.

MR. S. M. COLCORD, a former president of the American Pharmaceutical Association, was called upon by the chairman, and responded as follows:—

I was not expecting to be called upon to speak. I am not now in the drug business, consequently not an adulterator, not personally interested in the law, but am in the milk business, supplying pure milk. I am interested in this question as a matter of public welfare and consider it a question of vital importance. More than thirty years ago I served on committees to detect, expose, and prevent adulteration. The American Pharmaceutical Association had its birth in a convention of the best apothecaries in the United States, called for the purpose of exposing and preventing the importation of inferior, adulterated, or spurious drugs. A law was already upon the Statute Book, and this convention was called to state the facts to the government, and pray for the enforcement of the act for the public welfare. The convention found it to be a work of time, and that home adulterations were equally important, and that patent medicines seemed to be exerting a controlling influence. After two annual conventions a constitution and code of ethics were formed, and the convention adjourned to meet in the city of Boston as the American Pharmaceutical Association, with a Boston man for president, and here in this city of Boston was fought the great battle of adulteration. On the question of "admitting all drugs good of their kind" it was decided, mainly by Boston votes, that the large class of spurious, adulterated, and sophisticated goods was to be admitted no longer through our custom houses. The consequence was that all the distributing ports of the world soon found out that the United States was no longer to be the market for their worthless trash. Orders went out for goods of such a quality as would pass the custom houses, and it soon came about that foreign consignors sent no more poor goods to this country, and our dispensers became acquainted with a class of drugs heretofore unknown in our country, and now every one is satisfied with the law; no one is oppressed; dispensers, *well informed*, have no trouble in finding pure articles of fine quality, and everything is lovely in that direction. But how about patent medicines and home adulterations? Well, the new Association found itself born of "poor but honest parents," and not having arrived at a fighting age, voted that patent medicines or secret

[1] Concluded from page 256.

remedies were not a legitimate part of the dispenser's business, and as this was too big for them to handle, and as they had so much other useful work to perform, that they would have nothing to do with this question. Home adulterations continued to be reported upon year after year, the Association growing more critical and severe (without accomplishing anything) until the committees making the reports were threatened with private prosecution. It was then voted to change the committee so as to serve the drug market, and the Association has since done what it could by fostering investigation, science, and education as a preventive and controlling influence upon home adulteration.

As I am now out of the business I do not feel like talking upon this subject. The fact is, these people are all my friends, — the wholesale druggists, the retailers and dispensers, the prescribers, and the patients who have patience to take these adulterations, and my experience has been that I cannot shoot an unknown enemy at long range, without finding it a fratricidal onslaught with poniard and pop-gun.

This matter of home adulteration is not a thing that has grown up in the drug business. You might as well say the drug business grew out of adulteration. I presume in the beginning they started in the race together, but I think now that adulteration may be a little ahead. It has always seemed to me that many honest and honorable men in the drug business have come to think that what many people call adulteration, sophistication, and substitution, is an unavoidable and legitimate part of the business, and that having adopted the business they adopt these side issues as annexes to the law and the *profits*.

Now this law was not put upon the Statute Book by any action of the drug trade, neither was any remonstrance made to it that I am aware of, and the drug trade has had very little interference from the law, and it only desires to be let alone, and to do as it pleases, and feels abundantly able to settle points of quality with its customers without the interference of law. But still the fact remains that the United States Pharmacopœia is nearly a perfect standard of quality, fully recognized as a legal standard, with nothing ambiguous or undefined, and very easily conformed to by all persons qualified (even very poorly) to do an ordinary drug business; that by enforcing this law all are freed from disloyal and dishonorable competition in quality, and can have no reasonable objections to the law.

If we try this law fully enforced for awhile we shall find relief from all conflictions between honesty, conscience, and profit; we should have the confidence of our customers, and all parties would be benefited commercially, and the mercenary taint that clings so tenaciously to the drug business will be so far removed that few, if any, would be willing to have the law repealed or become a dead letter.

MR. HENRY CANNING, President of the Massachusetts College of Pharmacy, spoke as follows: —

Experience has shown that the President of the College of Pharmacy cannot be too careful in acting as its mouth-piece, for the reason that the institution is apt to be held responsible for all sorts of legislation touching the pharmacist.

As an individual, however, I trust that if any modification of this law must be made it may be only in the direction of making it stronger. It is eminently a law for the better protection of suffering humanity.

I was somewhat chagrined on hearing the report of the various adulterations in the line of food and drugs to find that so large a percentage of the pharmaceutical products examined had been found wanting, but the feeling was a little softened when I learned that the same report showed a much larger percentage of adulteration in important articles of food.

Again, I trust that if any change in this law be made it be only in the upward scale.

PROF. G. F. H. MARKOE spoke in favor of the present law as follows: —

MR. PRESIDENT, — I am heartily in favor of the law for the prevention of adulteration of food and drugs, and would be sorry to see it changed except in the direction of greater efficiency.

The remarks by the gentlemen who have spoken before me place the subject of the adulteration of drugs in its worst aspect. More than twenty years of practical familiarity with the drug market enables me to affirm that during all that time there never has been, and there is not now, any serious difficulty in getting good drugs, pure chemicals, and well-made, full strength pharmaceutical preparations from all reputable wholesale druggists or manufacturing chemists, provided the pharmacist or the physician is willing to pay a fair price for choice drugs and standard preparations. The sharp competition in the prices of goods, mainly introduced by unscrupulous dealers, who care nothing for quality, has a great deal to do with the adulterations and substitutions that are found in the drug trade, especially in the line of powdered drugs, which may be quite worthless, and yet appear equally as good as the powder made from a pure drug. A skillful drug miller can transform worm-eaten or rotten rhubarb into a nice-looking powder quite as handsome as that furnished by a prime article of Chinese rhubarb. Citrate of iron and quinine may contain two per cent. or twelve per cent. of quinine, and yet the two samples may appear to be alike; a careful assay alone will show the true character of the article. But although citrate of iron and quinine with less than the standard quantity of quinine is quite common in the market, and is bought by those who will not pay the price for the officinal article, yet I feel sure that a very large portion of all that is sold is of good quality, because the chemists who produce the largest part of all that is used in the country make an honest preparation, and also because the great bulk of all the dispensing business is in the hands of honest and capable pharmacists, who demand a guarantee of quality from those of whom they buy, and who know enough to reject that which is not fit for use.

The wholesale drug trade of the country, with but few exceptions, is in the hands of honest and honorable men, who would much rather deal only in the best grades of drugs and only in the products of the most reputable and skillful manufacturing pharmacists and chemists. The efficient enforcement of the drug law will compel the few firms who willfully force poor goods upon the market to mend their ways; and since there is little chance for underselling on goods of equal quality the ruinous competition which compels an honest man dealing only in honest merchandise to meet the prices quoted by dishonest dealers for articles bearing the same name and label, but far below the standard of purity and quality, this sort of unfair and unjust competition will be kept well in check by the law in question, and I feel sure it will

receive the hearty support of all well-meaning dealers.

A few words with regard to the pharmacist as distinguished from the druggist or wholesale dealer in drugs. I hold it to be his duty to closely watch all his supplies and to assure himself of their proper quality. The United States Pharmacopœia of 1880 contains concise and accurate descriptions of all officinal drugs and chemicals, together with statements of the adulterations and impurities to which they are liable, also giving good tests for purity and practical methods for the recognition of sophistications. This part of the work is so well done that no intelligent pharmacist has any excuse on the score of the lack of a sufficient guide and standard. Those who do not know enough to use this excellent standard must either employ some one competent to interpret and apply it for them or run the risk, under the law, of being ranked with those men who willfully transgress for the hope of greater gain.

W. W. BARTLETT, Ph. G., Vice-President of the College of Pharmacy, spoke as follows: —

MR. CHAIRMAN, — I am very much interested in this adulteration law, and have attended many of the trials and hearings that have grown out of it.

I am first vice-president of the Massachusetts College of Pharmacy, but come here in my individual capacity only. It is contrary to the policy of the college to take part in anything of a political nature, it being strictly an educational institution. I believe that the law should remain on the statute books just as it is. The changes now sought to be made in it are in the interests of those who have been detected in adulterating their goods and aim to make the law totally inactive. The best druggists in Boston favor the law as it is, and many have been present at the public hearings and have so expressed themselves openly.

The action of the Boston Druggists' Association in the matter of adulterations has not been clearly understood by all. By your leave I will read the following resolution, offered by myself, and unanimously adopted by that body, November 27, 1883: "Resolved, That the Boston Druggists' Association heartily condemns the practice of adulterating drugs and medicines, and will give its earnest support to any fair and legitimate means for suppressing the obnoxious business."

Physicians will have no difficulty in obtaining drugs and pharmaceutical preparations that are fully up to the standard of the United States Pharmacopœia of 1880 if they demand them. I make a practice of assaying my opium before making tincture of opium, and have found in every case the opium fully up to the requirements of the United States Pharmacopœia, 1880, when procured from a reliable source. I have also examined a sample of citrate of iron and quinine for a wholesale druggist in this city, which was the product of the laboratory of a reliable manufacturing chemist, and found it fully up to the standard of the United States Pharmacopœia, 1880.

These facts show that it is quite an easy matter to get reliable drugs and pharmaceutical preparations. The greatest difficulty that the retail druggist has to contend with is unfair and dishonest competition. The dealers in fancy goods having taken from us a part of our business, and established ruinous prices for the articles so taken the public immediately based the prices of prescriptions and drugs on these prices regardless of purity and quality, and many unscrupulous druggists have met these prices and furnished correspondingly bad goods.

I think that physicians should discriminate in favor of those stores where only strictly pure and standard goods are dispensed.

I believe that much trouble comes from the millers. I had occasion not long since to have a white preparation ground and I found a cubeb and some gum arabic in the tailings. On requesting the miller to allow me to visit his mill he objected, and I found that he did his grinding under lock and key.

In conclusion I would state that I think that the law as it is can be safely left in the hands of the Board of Health without working hardship or oppression to the honest pharmacist or wholesale druggist.

DR. DAVENPORT, in reply to a suggestion that drugs from some reputable manufacturer should be specified by the physician in prescribing medicines, stated that he considered it better to demand a good article and leave it to the discretion of the pharmacist to supply the drug from any manufacturer he might think proper, or from medicines manufactured by himself if he should choose to do so. In this way the responsibility for the quality of the goods is taken from the prescriber and is placed upon the dispenser, who is also stimulated to the selection or preparation of articles of standard quality and reliability.

WM. C. DURKEE, Ph. G., spoke as follows: —

I am especially glad to hear the last remarks of Dr. Davenport. The practice of specifying a particular manufacture of pharmacopœial preparations does not seem to me a good one, but one, should the custom largely increase, which will produce injury to both apothecary and doctor.

The apothecary having little occasion to practice by manufacturing, the knowledge which he may once have acquired, will become less inclined or able to apply the pharmacopœial tests for purity and quality to those few drugs or preparations which are not ordered by the name of some manufacturer or dealer. The responsibility of the apothecary ceases when he complies with the order of a physician who indicates the maker of the preparation he wishes dispensed, and the physician assumes all the responsibility for quality, as the manufacturer may reside in another State or country and not be amenable to Massachusetts law. Whereas if medicines are ordered by the officinal name only, the pharmacist is wholly responsible for quality, and if able to properly assay the officinal preparations, he is competent to manufacture them, and is entitled to a portion of the profit which would otherwise often go to any irresponsible foreign manufacturer who creates a demand for his preparations by advertising or otherwise.

I am heartily in favor of the law as it now stands, and believe it will do much to elevate the practice of pharmacy. It will help to do away with the competition of those who buy poor drugs and sell preparations from them cheaper than good preparations cost to manufacture. It will help us to furnish physicians with reliable remedies, thereby adding to the faith in and knowledge of medicine and increasing its usefulness.

The pharmacist should be held responsible for quality, but should be allowed to make, or choose the maker of the medicines he dispenses.

DR. GEORGE B. SHATTUCK called the attention of the Society to the bill lately introduced in Congress by a Pennsylvania representative to provide for the preparation and publication of a new pharmacopœia. The subject was an important one and had a direct bearing

upon the question then under discussion. The present Pharmacopœia had been prepared by the best experts in the country after careful consideration and consultation. As was shown by preceding remarks of some of the well-known pharmacists, who had added the weight of their presence to the meeting, the better the changes made in the work were understood the more they were approved of. The book had already been adopted as a legal standard in four large States, and was also the standard adopted by the United States Treasury Department. As many other excellent reasons readily suggested themselves why a new pharmacopœia was unnecessary and objectionable, and not one that he could think of in its favor, the speaker begged to be allowed to offer and move the adoption of the following resolutions: —

Resolved, That this Society is strongly opposed to a bill introduced into the National House of Representatives January 8th last, by Mr. Randall, entitled A Bill to Prepare and Publish a National Pharmacopœia for the United States. The Society believes that the present Revised Pharmacopœia is at the very least as good a work as is likely to be secured by the passage of this bill.

That all necessary legal authority which the present Pharmacopœia does not now possess can be easily given it.

That the complication which would necessarily arise from two pharmacopœias is undesirable.

Dr. F. H. Williams seconding the motion, the resolutions were unanimously adopted.

Mr. G. F. H. Markoe, of the Massachusetts College of Pharmacy, spoke against the bill and in favor of the present Pharmacopœia upon much the same grounds as those already given.

Adjourned at 10.30 o'clock.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

May 12, 1883. A Clinical Chart was exhibited by Dr. Green.

CASE RESEMBLING INFANTILE PARALYSIS, CAUSED BY IMPROPER DIET.

Dr. Minot reported a case of interest in relation to the diagnosis of infantile paralysis. A little girl, thirteen months old, who had been brought up on Mellin's food and Swiss condensed milk, had an attack of dysentery, followed by tenderness in every part of the body, especially the legs, and soon lost the power of moving the legs. When seen by Dr. Minot, three months afterwards, she was pale, delicate, very thin, the gums were spongy and black, the teeth (incisors) loose. She was intelligent, and could say a few words. The lower extremities appeared almost completely paralyzed, the only movement being a slight lateral one of the feet, and some flexion and extension of the toes. Irritation of the soles of the feet failed to produce reflex movement; irritation of the inside of the thighs, just above the knees, caused slight movement of the legs. The case strongly resembled one of infantile paralysis, but in view of the condition of the gums, and the general atrophy of the child, a change in diet was advised, together with iodide of iron and cod-liver oil. The medicine was not given, but the patient was fed with fresh cow's milk, bread, and broths. An immediate improvement took place, and the motion of the legs was soon restored. The child has since continued perfectly well, now for about three years.

Dr. Buzzard, who mentions a similar case in his Clinical Lectures on Diseases of the Nervous System, attributes the paralytic symptoms to a large quantity of uric acid in the blood, caused by the enormous amount of sugar contained in the diet. He thinks that minute crystals of uric acid are deposited in the connective tissue between the muscles, and cause so much pain as to render the muscles powerless.

Dr. Abbot remarked that when first introduced it was said of dialyzed iron that more than ten or fifteen drops was useless, but he had prescribed much larger doses with apparent advantage.

Dr. Ingalls said that he had always considered the tincture of the chloride by far the best preparation of iron, but within the past few years he had tried the dialyzed preparation, he thought with less good results. As to the excess of dose of the latter, was it not as with many other articles, the tincture of the chloride, for example; for after a few days the deep discoloration of the fæces had led him to think the doses larger than necessary.

HIGH TEMPERATURES AFTER LABOR WITHOUT OBVIOUS CAUSE.

Dr. Fifield spoke of the occasional occurrence of high temperature and pulse after labor, whether instrumental or unaided, where no definite cause could be traced and where no serious results had ensued, the patient meanwhile calling herself well and feeling no particular discomfort. Some of these cases seemed to be remittent with one or two days' interval. The last seen was given into his hands by Dr. Cutler. The patient, a primipara, thirty years old, had had a very hard instrumental labor. For several days the temperature continued at 104.5° F., and the pulse at 130–140, yet the patient perceived nothing amiss with herself. The lochia were not particularly offensive, and carbolized vaginal injections were frequently and regularly used. The lady was of a very nervous temperament. After these high figures had continued, with occasional remissions, for about twelve days, the pulse and temperature subsided and a good recovery followed.

Dr. Fifield said that he was at great loss to explain these symptoms. There was no septicæmia. Careful examination and inquiries revealed nothing otherwise abnormal. Dr. Fifield remarked that Dr. McClintock speaks of the great rapidity of pulse in some women after labor, the symptom having no particular significance.

Dr. Minot said that he had reported to the Society cases somewhat similar to those of Dr. Fifield. In each case the patient was of very nervous temperament.

Dr. Draper referred to cases reported by Teale, of Manchester, England, several years ago, of hysterical women in whom the temperature reached 122° F., in one instance verified very carefully.

Dr. Richardson stated that at the lying-in hospital there had been a number of cases where the temperature had run high for several days, with nothing to account for it except perhaps laceration of the cervix after severe labor. When the "surface" became normal and the laceration had healed the temperature fell; so distinctly, that it might be supposed that these

cases of high temperature had been due to some laceration.

DR. DOE said that in the *London Medical Times and Gazette* a case was recently reported in which the temperature after labor ran up to 106° F. The cervix was lacerated on one side. The uterus was washed out and the temperature fell immediately to 101° F., but rose again. The washing out was kept up for eight or nine days, the temperature rising to 104° F. in the intervals between the washings. Four days later, the washing having been discontinued, the temperature fell. The symptom was supposed to be due to the laceration alone.

THE INDUCTION OF LABOR.

DR. RICHARDSON gave the details of two cases of the induction of labor. One in a case of eclampsia where manual dilatation and version had been performed, the patient being delivered in a little over one and a quarter hours. The other in a patient in the last stages of phthisis where the labor had been induced by rupture of the membranes high up. Labor started up within five minutes after the escape of the liquor amnii.

DR. SINCLAIR remarked that the ease of dilatation was accounted for by the fact that the patient was a multipara.

In answer to Dr. Reynolds, Dr. Sinclair stated that he had performed manual dilatation with delay varying from five minutes to four hours, and declared that there was no bag in existence equal to his own finger. Manual dilatation was perfectly safe if the operator's head was steady and his hand proceeded accordingly. Nothing would take the place of the finger. If the operator jumped about and withdrew his finger and generally lacked steadiness of purpose, he would fail, and he would regret his failure.

DR. RICHARDSON stated his belief that Barnes' dilators simply start up labor. He had never seen any further effect from their use. In any case where the patient could take ether he would never use any means but manual dilatation. Dr. Richardson asked if it were not a fact that the cervix dilates by uterine pains when Barnes' dilators are used, and not by any dilating force exerted by the dilators.

DR. SINCLAIR observed that manual dilatation was being gradually and quietly adopted in England, and was resorted to a good deal everywhere. He said there were sometimes troublesome cases, and referred to that of a primipara at the eighth month, where dilatation occupied four hours and the woman died of secondary hæmorrhage at the end of twelve days. This was somewhat discouraging, but this was the longest time required he had ever met with. Tearing the cervix ought not to occur; one must use patience and wait till the parts are thoroughly soft and dilated.

HÆMOPTYSIS IN THE COURSE OF PUERPERAL SEPTICÆMIA.

DR. HOSMER reported the following case:—

A patient, something more than thirty years old, dated the commencement of her fourth pregnancy from October 25, 1882. Early in the following February she had a severe fall upon the ice, and on the 22d of the same month she noticed flowing.

She was first visited March 15th, and the usual precautionary measures were advised, but without avail, for ten days later, March 25th, the fœtus was expelled. A puerperal septicæmia was soon developed, and in connection with it there came a rather long succession of chills which were connected with thoracic trouble. There was severe pleuritic pain on the right side, condensation of the lung tissue over a small area in the middle of the right back, and hæmoptysis, which in varying degree continued for many days. The expectoration, effected without much cough, did not conform to the ordinary pneumonic standard, but contained a large proportion of fresh, bright blood. The question was as to the precise condition of the lung which occasioned the hæmorrhage. Reference was made to the *Boston Medical and Surgical Journal*, in which, in the issue of November 20, 1879, under the head of Phlebitis of the Lung, was reported a case that presented the same symptom which was thought to be an unusual one by reason of the conditions with which it was associated.

DR. FITZ said that he was under the impression that Dr. Wyman used the term as synonymous with thrombosis. Hæmorrhage is a frequent symptom of pulmonary embolism; persistent hæmorrhage would suggest abscess or gangrene during the progress of which the hæmorrhage continued. Hæmoptysis, however, is a result of embolism only in the case of the passage of relatively small particles into branches of the pulmonary artery — an obstruction of the primary branches of which results in sudden death — before the phenomena of hæmorrhagic infarction can occur. In the woman there was probably uterine thrombosis followed by pulmonary embolism.

JUNE 9, 1883.

METHOD OF MANAGEMENT OF FACE PRESENTATION.

DR. RICHARDSON reported two cases of face presentation in which delay had been occasioned by the head not being fully extended. The lack of extension being remedied, rotation had taken place and the children had been born.

ACUTE ECZEMA IN PREGNANCY.

DR. ABBOT reported the case of a primipara who during the first month of her pregnancy had become covered with an eczematous eruption, in size from a small point to a surface an inch in diameter, accompanied by considerable itching, here and there slight vesication, followed by furfuraceous desquamation of the cuticle, which was finally well in three or four weeks. Such a case is described by Dühring as a form of acute eczema. The patient received no treatment except a borax wash to relieve the itching. The whole body and extremities were covered by the eruption, which was supposed to be due to the suspension of the catamenia by pregnancy. The patient had never shown any sign of eczema before, except a slight irritation at times close to the alæ nasi.

PROLAPSE OF THE ANTERIOR WALL OF THE VAGINA DURING LABOR.

DR. LYMAN reported a case of delayed labor with this complication. As the head descended there lay in front of it what appeared to be the thickened anterior lip of the uterus, and which became thicker and thicker, resisted efforts to restore it, and was found to be the anterior wall of the vagina. This delayed the labor about an hour. For several days after the labor there were pretty decided symptoms of cystitis, but these passed off, and the patient made a satisfactory recovery.

Dr. Richardson said that he had seen the condition several times at the hospital or with the students, always in multiparæ and in women in a markedly debilitated condition, and preceded by trouble with the bladder which was in the fold.

Dr. Lyman said that the patient had had no trouble with her bladder previously. She had consulted him a year before for a very badly lacerated cervix and perinæum, and almost universal eczema, owing to which she was advised not to undergo operation. Under general treatment she improved, went home to Minnesota, got well of the eczema, conceived, and came on again to be confined. Dr. Lyman remarked that the case illustrated how well women get along sometimes with badly lacerated perinæum, cervix, etc., the cervix showing complete eversion. All the uncomfortable symptoms disappeared, and since her confinement the patient has been as well, almost, as any woman.

Dr. C. Ellery Stedman remarked that he had seen the same appearance, the vaginal fold being as thick as his thumb.

Dr. Green thought it strange that with prolapse of the anterior vaginal wall and a torn perinæum there was not more trouble. As to treatment, if the fold could be pushed up, that would be sufficient; otherwise, in his opinion, the forceps should be used at once.

Dr. Richardson remarked that version would be better, as avoiding a dragging down, with forceps included, of the very thing it is desirable to avoid.

Dr. Lyman said that if he had put in forceps he would have risked vesico-vaginal fistula; but he would not interfere unnecessarily.

Dr. Green observed that the head might be too low for easy version, and it was a fair question whether forceps or the continued pressure of the head were the worse. It seemed to him that the forceps might have been used, the perinæum being torn, if the head were depressed somewhat so as to avoid pressure against the anterior wall. Either one or the other process should be adopted rather than let the case go on a long time without aid.

Dr. Richardson observed that it should be recollected that in version a different diameter of the head is coming through the pelvis, and the rotation need take place only at the last minute.

Dr. J. L. Sullivan, of Malden, said he would like to call attention to the different experience of different physicians. He had had twenty-five hundred cases of labor and never a face presentation.

Dr. Richardson said that in the lying-in hospital three of the six cases of face presentation were in women with deformed pelves. In answer to a question by Dr. Lyman, he should think it was very seldom that a woman would suffer from hæmorrhage in case of low attachment of the placenta before the sixth or seventh month. He never would allow a case to go on without delivery if the child were viable.

Dr. Lyman gave an account of a case of immense suppurating unilocular ovarian cyst. The woman died twenty-four hours after ovariotomy.

Dr. Sullivan reported a case to which he had been called in consultation, and asked what ought to have been done. The woman was six and a half months pregnant, not for the first time. She had a convulsion, being in the advanced stages of Bright's disease. It was impossible to dilate the cervix in consequence of a whipcord like contraction during the hour or hour and a half of effort, but she was not under ether. Suddenly she became comatose, and died in ten minutes. The urine was scanty, moderately albuminous, and perfectly loaded with casts of all descriptions. There had been no uterine action. In another case, not long ago, Dr. Sullivan succeeded in dilating and inducing labor, and everything went on well.

Dr. Richardson suggested that the uterus might have acted differently under complete anæsthesia.

Dr. Sullivan questioned further what course should have been pursued had ether been administered without result. The question propounded was this: What ought to be done in such a case provided a whipcord constriction persisted after bleeding and etherization, or any other suitable means, had proved useless in causing relaxation and dilatation. In the case related the patient suddenly died just as ether was brought into the room. The remarkably feeble pulse and feeble condition of the circulation led him, right or wrong, to postpone venesection until the effects of ether had first been ascertained. Before ether could be procured death occurred, probably from cerebral hæmorrhage.

The question actually propounded, or intended to be propounded, by him was this: Would it be proper to deeply incise the os uteri in such a case should the whipcord constriction of the internal os persist after bleeding and ether had been pushed to the full extent of safety. In other words, the inquiry relates to a *hypothetical* case, the possibility of such having been suggested by an actual one.

Dr. Abbot observed that it was well known that apoplexy was a not uncommon result in such cases, and if it was the cause of the symptoms in the one reported nothing could probably have been done to relieve it. He had had a patient, however, a boy, who was comatose, completely, for a week, in the course of Bright's disease, and recovered entirely so far as the coma was concerned.

Dr. Sullivan remarked in regard to venesection that it was contra-indicated, yet if the patient had lived and the ether had failed he would have bled. As to the condition of the cervix he could dilate so far, but no more, with repeated efforts.

NEW YORK STATE MEDICAL ASSOCIATION.

The New York State Medical Association has just issued in pamphlet form a report of the proceedings of the convention held in the city of Albany February 4 and 6, 1884, at which the Association was organized on a permanent basis, together with a list of founders, representing the various counties of the State, to the number of 168.

THE CANVASS OF THE STATE. THE "CODE" QUESTION.

At the first meeting, February 4th, Dr. Gouley made a report of the canvass of the State which had lately been completed. In regard to the circular which had been sent to every member of the regular profession in the State, so far as known, the following figures were given: —

The proof is found to contain the names of	5219
Since the appearance of the proof new names have come in to the number of	67
Total, carried to next page	5286

Which number, added to the original, gives a total of	5286
Since the beginning of the canvass there have died	83
	5286
Number of names stricken off from other causes	201
Leaving a total (given in the corrected catalogue) of	5002
Number of those who have not expressed their preference	1142
Total number of votes recorded	3860
For the National Code (corrected number)	2547
For the "New Code" (corrected number)	1040
For no Code (corrected number)	239
Unclassified (corrected number)	34
Total	3860

The canvass of the State Medical Society showed the following figures: —

For the National Code	193
For the "New Code"	134
For no Code	19
Uncommitted	36
	382

In some remarks on the report of the canvass Dr. Gouley urged speedy action in the formation of a separate association on the ground that there was not the least chance that the National Code of Ethics would be reënacted by the Medical Society of the State of New York as long as a two-thirds majority was required. There was not a two-thirds majority, and he did not believe such a majority could be obtained in five years or more.

DR. FLINT'S ADDRESS.

DR. AUSTIN FLINT, SR., made an eloquent address, in which he gave the recent history of the conspiracy which culminated in the adoption of the New Code by the State, and which first publicly made its appearance in the medical law of 1880, and also some account of the measures taken to counteract its baneful influence. It opened as follows: "It is more than a year since I have publicly spoken to an audience of friends on the questions which have at last divided the medical profession of the State of New York. As you all well know, thus far the battle-field in the warfare against the honor and dignity of the profession has been mainly in the city of New York. In the city of New York the conspiracy which brought about this deplorable conflict that has been forced upon us, had its inception. The attack upon the most sacred traditions of our profession was there made with a malignant rancor that can only be fully appreciated by those who have been personally involved in this unhappy contest. I say it in all modesty, but we of the city of New York come before you as veterans from the front, bearing scars. If we venture to offer suggestions with regard to future action, if we beg you to learn a lesson from our experience, it is because we are unhappily too familiar with the arrogance and the unscrupulous methods of our enemies within the profession. Our experience teaches us that but one course is now open to those who are unwilling to remain in the false and humiliating position in which we are placed. The proper course is for us to organize a new State Association, to be composed exclusively of those who refuse to countenance professional relations with irregular practitioners."

The address was concluded in the following words: "The issue has been forced upon us. We stand in the actual fact of a divided profession. The State Society and Society of the County of New York have seceded from the regular profession of the United States. We made no movement looking to the formation of a loyal State Association until the most vigorous efforts to redeem the existing societies had signally and hopelessly failed. We are now cast out of fellowship with the regular profession of this great country, as represented in the American Medical Association and in the medical societies of other States. We must redeem the State of New York. There remains but one course to pursue, and that is to form an association of our own. The bitter fight, the disgraceful spectacle of a contest between members of a devoted and honorable profession, are things of the past. The war is ended. Let us organize and live together in peace, working hand in hand for the advancement of the science of medicine. Let the men who are so blind or so misguided as to think their course is right, or who cannot resist the temptation to take tribute from those who persist in supporting the enemies of truth and of our universal science of medicine, go their own way and consult on terms of equality with any and all 'legally qualified practitioners of medicine,' whatever form of charlatanism they may assume! I hope, Mr. Chairman, that a New York State Medical Association will be organized to-night in affiliation with the regular profession of the United States; that the existing county societies whose membership is loyal will put themselves at once in affiliation with the new State Association; and that in counties in which the existing societies cannot be brought in bodily new associations will be promptly organized, to be composed exclusively of members of the profession who uphold the National Code of Ethics."

PLAN OF ORGANIZATION.

The plan of organization adopted provided: (1.) That the State should be divided into five geographical districts. (2.) That a nominating committee of eleven members should be created. (3.) That the nominating committee should name the various officers, subject to the approval of the Association, and also two members from each district, who, together with the titular officers and one member appointed at large by the President-elect should constitute the Council for the management of the affairs of the Association. (4.) That the Council should complete the organization, prepare a constitution and by-laws, in accord with this plan, to be presented at the next meeting of the Association, and file articles incorporating the New York State Medical Association and also county associations as branches of the latter. . . . (8.) That the initiation fee should be five dollars, and the annual dues three dollars. (9.) That the Code of Ethics, which should form an integral part of the By-laws of the Association, should be the same as that adopted by the American Medical Association. (10.) That the Association should hold annually one session, which should last three days or more.

A resolution was also adopted to the effect that all physicians in the State of New York who were in good standing in the present county societies, and who subscribed to the Code of Ethics of the Association, could become members thereof upon paying the initiation fee and signing the Constitution and By-laws.

MEETING OF THE COUNCIL.

At a meeting of the Council held after the adjournment of the Association, Drs. A. Flint, Jr., J. W. S. Gouley, and N. C. Husted were appointed as a special

committee on the preparation of a constitution and by-laws for the Association. Dr. A. Flint, Jr., Dr. Van de Warker, and Dr. Gouley were appointed a committee to secure the coöperation of a medical journal in sympathy with the wishes and interests of the Association.

On motion of Dr. Van de Warker it was resolved that the members of the Association should be designated Fellows, and Drs. E. M. Moore, A. Flint, Jr., and the Treasurer, Dr. J. H. Hinton, were appointed a committee to prepare a seal for the use of the Association and a form of certificate of fellowship.

Recent Literature.

Opera Minora, A Collection of Essays, Articles, Lectures and Addresses, from 1866 to 1882, inclusive. By Edward C. Seguin. New York: G. P. Putnam's Sons. 1884. x., 687 pages.

Dr. Seguin has been a voluminous writer, has done much to bring to the notice of the profession the latest results of research in nervous pathology and therapeutics, and has himself aided in the extension of our knowledge. His papers and reported cases are to be found in many medical periodicals, scattered widely and not always easily accessible. It is, therefore, a satisfaction to have them collected in one volume.

About eighty essays, etc., are reprinted, beginning with three published while Dr. Seguin was house physician of the New York Hospital. The majority of the subjects either relate to or are closely allied to the nervous system; one of the earliest of these is a paper in regard to aphasia published in 1868, which is one of the longer articles. Among the more important subjects may be mentioned Description of a Peculiar Paraplegiform Affection (tetanoid paraplegia), the first cases of spastic spinal paralysis reported as a distinct affection. Contribution to the Study of Localized Cerebral Lesions and a second article on the same subject. Lecture upon the General Therapeutics of the Nervous System. A paragraph at the close of this lecture is well worth quoting, "Let me close this rather fragmentary lecture, by calling your attention to something which is not wholly extra-medical. I allude to the care of your patients' spirits, their emotions and fancies if you will. Never let *alarm* be one of your medicaments. If necessary, in order to bring about a reform of bad habits, lay the picture of consequences before your patient truthfully, but not in the language of exaggeration. Even in hysterical cases you need not be so frank as to hurt your patient's feelings; it will often do if her relatives know precisely what you think of the value of the symptoms. In cases of mental disorder, pray do not forget that even very maniacal or melancholic patients attend to and remember all your words and actions, and will treasure any kind and careful behavior of yours as well as bitterly recall any unkind or hasty phrases and acts. As a general therapeutic rule, I would have you be as anxious to avoid wounding the sensibilities of your poor or wealthy patients as of injuring their tissues."

There are eight lectures on the Localization of Spinal and Cerebral Disease, several articles on the diagnosis of different diseases, and the importance of an early diagnosis. The papers relating to the value of certain drugs and the dosage in treatment of nervous diseases are well worth reading.

Many interesting cases will be found reported in more or less detail.

Of course the different papers vary in importance and in value, there may be some statements which the author would now modify if he were writing on the subject again; but there is much of permanent value in the book, apart from the interest to be found in it as the record of the mental and professional growth of one of our foremost neurologists.

Transactions of the American Gynæcological Society, Vol. 8, for the year 1883. New York: D. Appleton & Co.

This volume appeared with commendable promptness less than four months after the meeting of which it is the report. We regret to see that in the change of publishers, whether inadvertently or intentionally, the color of the paper has been changed from that of the preceding volumes to one several shades nearer to a pure white: the typography of the title page is also changed, not to our taste for the better.

The President, Dr. Gilman Kimball, gave as his annual address A Biographical Sketch of Dr. Nathan Smith, Founder of the Dartmouth Medical College, who was the second in this country to perform ovariotomy successfully. As Dr. Smith was at the time unaware that McDowell had operated at all, his operation was "as truly original as the first" although performed nine years later. Ephraim McDowell is certainly to be regarded as the "father of ovariotomy" in point of time; but Dr. Kimball pleads with much justice that "in point of absolute merit Nathan Smith is entitled to the same honor as that accorded to McDowell."

Dr. R. S. Sutton's paper on Cleanliness in Surgery shows how generally the principles of Listerism have been adopted, although all surgeons do not accept them in their entirety. To the greater attention to cleanliness and the avoidance of contamination of wounds, brought about by Lister's teachings, are to be ascribed the greater measure of success in the surgery of the present day.

Dr. A. H. Smith calls renewed attention to the great value of hot water in secondary hæmorrhage after pelvic operations, especially in plastic operations, even when the bleeding occurs from moderately large vessels. The water should be at a temperature of 115° to 120° F., and to be most efficient should be carried directly to the bleeding surface. As operations are sometimes lost by the supposed necessity of cutting stitches in order to reach and tie bleeding vessels for secondary hæmorrhage, the efficiency and easy application of this hæmostatic should not be forgotten.

Dr. C. D. Palmer contributes an excellent paper on the ætiology and treatment of dysmenorrhœa, in which he expresses the belief, now held by many gynæcologists, that, although undoubted cases of so-called obstructive dysmenorrhœa do sometimes occur, painful menstruation is essentially a neurosis. Organic disease may or may not be associated with dysmenorrhœa; but the neurotic condition is the only feature in most cases. This condition is generally an expression of a disordered or highly developed nervous system: treatment should therefore be directed to the constitutional disorder, and local treatment be resorted to only when general treatment has failed.

Dr. E. W. Jenks suggests a New Method of Operating for Fistula in Ano which he has twice employed with complete success. The method is briefly as follows: The fistulous tract is incised in the usual way, care being taken to incise the muscular fibres of the sphincters at right angles. The pyogenic membrane is then carefully dissected out, bleeding vessels secured by torsion or ligature, and the parts thus laid open are then closed with deep sutures much in the same way as in the operation to close a ruptured perineum. Dr. Jenks does not claim that this method is applicable to every form of anal fistula; but he believes it to be the best method in a majority of cases. The advantages of the method are that a long convalescence is avoided, union is secured by first intention, and subsequent incontinence prevented.

Dr. C. C. Lee contributes a paper of great interest on the Management of Accidental Puncture and Other Injuries of the Gravid Uterus as Complications of Laparotomy. Nothing can be more appalling to the operator than to plunge a trocar into the gravid uterus, thinking it to be an ovarian cyst; yet this accident has happened to careful surgeons. Dr. Lee shows, however, that this accident is not necessarily followed by abortion, especially if the ovisac is not opened: he also formulates the treatment that should be pursued according to the nature of the injury.

Dr. R. B. Maury's paper on Rectal Disease Considered in its Relations to Disorders of the Uterus is an inquiry as to what extent certain morbid affections of the rectum are due to uterine disease. Since "the rectal, uterine, and vesical circulations are parts of one and the same vascular system," it is easy to see that any important disturbance in the nutrition of one of these organs must have a marked effect on the others; and Dr. Maury illustrates this effect by cases under his observation.

The remaining papers are by Dr. Johnson on Superinvolution of the Uterus; Dr. Reamy on a Rare Form of Abdominal Tumor; Dr. Campbell on Congenital Fissure of the Urethra, with Exstrophy of the Bladder; Dr. Jackson, Is the Extirpation of the Cancerous Uterus a Justifiable Operation?; Dr. Emmet, A Study of the Ætiology of Perineal Laceration, with a New Method for its Proper Repair; Dr. Byford, Remarks on Chronic Abscess of the Pelvis; and Dr. Engelmann, Ergot: the Use and Abuse of the Dangerous Drug. Dr. Barker's memoir of the late Dr. James Dowling Trask concludes the volume.

We are sorry that it has seemed good to the Society to omit the valuable index of gynæcological and obstetric literature which has previously found a place in these Transactions, and hope that the omission is only temporary. C. M. G.

Practical Pathology: A Manual for Students and Practitioners. By J. SIMS WOODHEAD, M. D., F. R. C. P. E. Edinburgh: Young J. Penthead. 1883.

This work is intended rather as a guide in the preparation of specimens for microscopic examination than as a systematic treatise on pathology, and as far as it goes is admirably adapted for its purpose.

The first part of the book is devoted to a description of the modern methods of preparing and coloring tissue. The value of the aniline colors for differential staining is prominently brought forward, and numerous formulas for their use are given.

The principal organs of the body are considered in the second part, commencing with the liver. A description of the normal histology is first given, and then follows a consideration of the most ordinary changes, which are met with. Then the methods best adapted for the preservation of each particular specimen for microscopic examination are dwelt upon; and lastly the appearances as seen under the microscope. These last are illustrated by beautifully colored plates, which add greatly to the attractiveness of the book, as well as giving an admirable idea of how really good sections should look when properly treated and colored.

The importance of always associating the gross appearances with the histological changes is a practical point strongly insisted upon by the author, and one often overlooked. For it is hard to realize that the aggregate of such slight changes as can be detected in the ultimate constituents of an organ can give rise to such marked differences in its color, size, or shape when regarded as a whole.

The book will be of value to those who wish a ready reference for practical work, and who have only occasional opportunity for it. It is to be feared, however, that the style in which the work is issued will enhance its cost so much that it will place it beyond the reach of many to whose library it would be a welcome addition.

An American edition of this work has just been issued by Henry C. Lea's Son & Co., which shows a little the wear of its English predecessor, but which from its lower price will probably be more popular.

Bacteria. By DR. ANTOINE MAGNIN and GEORGE M. STERNBERG, M. D., F. R. M. S. New York: Wm. Wood & Co. 1884.

The first part of this book is a translation of Dr. Magnin's work, and gives the classification of bacteria, from a botanical point of view, as presented by Cohn. This part of the book has value as affording a means of identification of the different forms that come under observation. The morphological characteristics of these parasites are now recognized to be of very uncertain value since the great variation in form under different conditions of growth has been discovered. This is fully recognized by the author, who devotes considerable space to a consideration of their physiological action and its value in determining species.

The latter part of the book is devoted to a résumé of the work done upon each of the diseases with which the micro-organisms have been found to be associated. With this is joined some original investigations undertaken by Dr. Sternberg, which, however, are so incomplete as to fail to carry conviction that all sources of error were excluded. There is also a marked tendency on his part to see in any rather indefinite form described by others a close resemblance to a micrococcus discovered by himself in a form of septicæmia produced by inoculating rabbits with human saliva. This has not been accepted as yet by the most competent observers as differing essentially from other forms of septicæmia following the introduction of putrefying substances.

At the end of the book is a very valuable and complete bibliography of the works on these minute parasites.

Medical and Surgical Journal.

THURSDAY, MARCH 20, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE DRUNKARD AND THE DOCTOR.

"FOR the gentlemen of the faculty of physic, I must frankly own that I see no special reason, why they in particular should apply themselves to the study of the law; unless in common with other gentlemen, and to complete the character of general and extensive knowledge; a character which their profession beyond others has remarkably deserved. They will give me leave however to suggest, and that not ludicrously, that it might frequently be of use to families upon sudden emergencies, if the physician were acquainted with the doctrine of last wills and testaments, at least so far as relates to the formal part of their execution."

Such was the opinion of the learned Blackstone as expressed in his lectures at Oxford one hundred and thirty years ago, and we have no desire to express a contrary opinion. We doubt if a little knowledge of the law is any less dangerous than a little knowledge of medicine. But certainly we believe, and no one will deny, that it is desirable for a physician to consider how his actions would appear in the eyes of twelve individuals selected at random from his peers. Every surgeon, certainly, though gifted with but a sluggish imagination, must sometimes picture himself as a defendant before an intelligent jury and his now grateful patient transformed into an indignant plaintiff. It is not wholly superfluous to consider some of the possible conditions in which the vagaries of a jury may be perilous to the doctor's pocket and peace of mind. He who has considered beforehand will act most intelligently when action becomes necessary.

In what follows there is no desire to interpret law, but simply to suggest some unusual questions that may be presented to the surgeon at any moment and the possible position that may be taken by a jury in reference to them.

Not long ago a drunken man was the victim of a severe accident to his arm which necessitated amputation. He had suffered a compound fracture with severance of arteries and nerves. The arm hung only by ribbons of the soft parts, and the venous hæmorrhage was restrained with difficulty. The accident had not entirely sobered the unfortunate. He had no friends with him at the time of the accident, and it could not be found that he had any relatives in the city. The necessity for amputation seemed evident to any man in his senses, but the operation was persistently refused by this inebriated individual.

The man had the appearance of one able to comprehend the true state of affairs could he only be allowed time to return to himself, but the venous hæmorrhage was so great and so difficult of control that delay was impossible; it was immediate amputation or death. In this instance the surgeon proceeded with his preparations, and received at last a somewhat reluctant consent to be sure, but one that justified him in the necessary action. But the refusal was sufficiently delayed to raise the question how far the surgeon may proceed in opposition to the will of a patient whose reasoning powers are temporarily destroyed by the effects of alcohol.

It is an axiom in surgical practice that no operation, not even the slightest, can be performed against the will of the patient or his or her guardian. It is the surgeon's duty to advise whatever procedure may be necessary, but before doing any operation it is imperative that he shall receive consent. If he does otherwise he invades the right of the individual and lays himself open to a criminal charge for assault or to a civil suit for damages. If a man deprived of his senses by a fracture of his skull were taken to a hospital, the surgeon would be justified in doing what seemed necessary; if he retained his senses sufficiently to remonstrate nothing could be done without the consent of friends.

Were the patient entirely deprived of his senses by alcohol, in other words dead drunk, possibly the surgeon might be justified in removing an arm so evidently destroyed as the one described above, especially where his inactivity would be so manifestly the cause of death. In such a case the law would demand of him only the exercise of ordinary judgment and skill if he chose to act, though we doubt if it would hold him responsible if he refused. Certainly he would run some risk in either case of being called before a jury to answer for his judgment. If the case will admit of delay there is no doubt the individual should be allowed to regain consciousness. Only in the plainest case and after all possible precautions in the way of consultation and explanation to by-standers should the surgeon snip the few shreds of skin that connect the crushed member with the body.

Were the patient only deprived of his reasoning powers, and did he protest against what seemed to him mutilation, however evident his drunkenness no surgeon would be justified in touching him. He might advise and entreat, and perhaps threaten, but further than that he could go only at his peril. A merely drunken person does not lose his responsibility for his own acts. Responsibility presupposes the ability to choose one of two lines of conduct, and inferentially the right to accept or refuse medical aid for himself. He may be held responsible for the failure to provide such aid for those under his care but not for himself, and any one who dared put in force the most evident principles of surgery should expect to find himself face to face with a jury worked up to frenzy at so evident an outrage on the independence of an individual.

Any person must interfere to prevent an active at-

tempt at suicide, but to prevent the passive suicide above mentioned is an entirely different matter.

Would the case be different were it known that the drunkenness was the result of alcohol administered feloniously, and not absorbed by the free will of the sufferer? No matter how benevolent the surgeon nor at what sacrifice of personal comfort he may act in regard to the matter, we doubt if he would be upheld by a jury in supposing that his unfortunate patient had lost any portion of his right to decide on the acceptance or rejection of surgical advice. That he had been the victim of rascality to such an extent as to deprive him of his senses would not justify any one in infringing on the right to resist mutilation.

Does the medical aspect of the case differ from the surgical? Would a physician be justified in administering by force an emetic to a drunken man who has been accidentally poisoned, in the absence of his friends, in spite of the man's remonstrances? Certainly the act is quite as much an infringement of his personal liberty as the surgical procedure, and we feel sure a jury might so regard it. Were the emetic administered by a subcutaneous syringe the case would approach nearer the surgical basis, and might well be regarded as an aggravated assault, though perhaps the absence of mutilation would make the offense less rank in the jurors' nostrils.

A drunken woman, dangerously flowing, might well regard the physician's attempts to determine the cause of the hæmorrhage as an assault; and it is already an established principle that the consent of a woman must always be obtained before an examination. Were a woman who had been examined when insensible from drink to learn of it and resent it afterwards might not a jury be brought to regard the procedure as an aggravated assault, that the physician had taken advantage of the woman's condition to do something he would not have dared to do had she retained her senses?

The conclusion of the matter is simply to emphasize the necessity on the part of medical men of respecting to the uttermost the rights of individuals. Such a combination of circumstances as we have mentioned will rarely happen; ordinarily the presence of friends will take the burden of responsibility from the surgeon's shoulders. Should such a case as has been mentioned present itself the surgeon will do well to follow the principles we have laid down. Possibly it may seem inhuman to allow a man to die simply because he is drunk. It seems inhuman to allow people to die simply because they are too ignorant to accept wise counsel, but it is sometimes inevitable. Every individual has the right to bear his congenital deformity unrelieved, his unsightly growth unremoved, to bear his pain without an opiate, to leave his fractured bones to unite as they will or not at all, to die with his crushed limb unamputated if he chooses; his diseases and his life are his and not the doctor's. One can as little force a man to follow a certain line of conduct in regard to his own health, if he does not to injure others, as in regard to religion.

stain. Were doctors infallible, were the practice of medformula

icine restricted to those fitted to undertake it, the case might be different; but in a community where so little distinction is made between doctors who have fitted themselves for the practice of the profession and those who arrogate to themselves the title it is proper that their powers should be carefully circumscribed.

SHALL THE UNITED STATES PHARMACOPŒIA BE THE LEGAL STANDARD FOR DRUGS IN MASSACHUSETTS, OR SHALL IT BE SOME ONE OF SEVERAL COMMENTARIES OR DISPENSATORIES?

IT is reported in the daily journals that a majority of the present Legislative Committee on Public Health, apparently influenced by certain wholesale druggists of this city who have been prosecuted by the State Board of Health, Lunacy, and Charity for selling adulterated drugs, intend to report a bill amending the present Adulteration Act. They would make that one of the several excellent commentaries, which have been published as private enterprises, which its authors have seen fit to entitle the United States Dispensatory, the legal standard in Massachusetts for all the medicines mentioned therein instead of the United States Pharmacopœia itself upon which it is based. Any such change in the law would be very disastrous, and we shall presently give a few of the many reasons why it should not be done, but in this connection it will be proper here first to consider by what authority the United States Pharmacopœia and the particular commentary thereon, entitled the United States Dispensatory, have severally been prepared.

The United States Pharmacopœia is the official code for the preparation of medicines issued by the authority of a national convention for its revision composed of not more than three delegates sent by the several incorporated medical societies, medical colleges, colleges of pharmacy, and pharmaceutical societies throughout the United States, the American Medical Association, the American Pharmaceutical Association, the Surgeon-General of the Army, of the Navy, and of the Marine Hospital Service, which has met at Washington, D. C., every ten years since 1820. It has thus a national origin as far as possible, not being the direct act of the national government itself. It has, however, received the authoritative sanction of the national government, at least ever since the act of Congress entitled An Act to Prevent the Importation of Adulterated and Spurious Drugs and Medicines, approved 26th June, 1868, when it was made the United States Treasury Department standard by which all imported drugs and medicines were to be tested in reference to strength and purity. Moreover, an act is even now pending before Congress to make it the standard in a national adulteration law almost identical with the present law in this State. In 1881 it was made the standard under very similar laws in New York and New Jersey, and subsequently in Louisiana.

In January, 1833, Drs. George B. Wood and Frank-

lin Bache, both of Philadelphia, and members of the Convention for the Revision of the Pharmacopœia in 1830, issued their private copyrighted work, which they were pleased to entitle the United States Dispensatory. In its preface they said, "We have, moreover, a national pharmacopœia which requires an explanatory commentary." "On these accounts it is desirable that there should be a Dispensatory of the United States." "But though precedence has been thus given to the Pharmacopœia of the United States those of Great Britain have not been neglected. Therefore, as it itself says, "the United States Dispensatory may very properly be considered as a commentary upon the United States *and the British Pharmacopœias*," and making the United States Dispensatory the legal standard would make the British Pharmacopœia equally with the United States Pharmacopœia the legal standard in this State.

As, however, it is only one of three very excellent commentaries upon the United States Pharmacopœia which have thus far been published as private undertakings it seems, indeed, a very strange idea to place this one in authority over and above the very work upon which it is itself based. Why should this particular commentary by Wood and Bache be thus honored rather than either one of the other two, the so-called National Dispensatory by Drs. Stillé and Maisch, likewise of Philadelphia, or the still later work, The Companion to the United States Pharmacopœia, by Drs. Oldberg and Wall, which has been just issued by the publishers of the United States Pharmacopœia itself? In short, the motive for this attempt to replace the present legal standard, which is the work of a representative national convention, on the sales of which, moreover, the compilers do not receive one cent of personal gain, — for the royalty of forty cents upon each copy sold, which is paid their committee of publication by the publishing house, is devoted entirely to the *repayment of only the actual expenses incurred* by the members of that committee in their work upon the Pharmacopœia itself, — is not *at first* apparent.

As merely a commentary upon the Pharmacopœia all the authority the Dispensatory has is naturally based upon that work, and it must therefore be subject to a revision at the least as often as is that work itself. Unlike the Pharmacopœia, however, which can have its standards changed only once in ten years, and that by the act of the majority of the national convention of delegates representing the wishes of the medical and pharmaceutical interests of the entire country, all the various dispensatories, as the private property of their authors, are subject to change any time at the will of one or two men. As also all three of the commentaries or dispensatories are more costly works than the Pharmacopœia, any one of them being made the legal standard would be a source of increased expense to the public and to druggists, as well as put us out of accord with the laws in other States.

A much more vital objection (and here probably is to be found the motive for changing the legal standard) as regards the efficient execution of the law is this, that with the Pharmacopœia as the standard the all-important question of exactly what is the legal standard is capable of much more easy solution than it would be were any one of the several dispensatories the standard. This is plainly seen by taking for example the much discussed subject of the legal strength of tincture of opium or laudanum. According to the United States Pharmacopœia, 1880, one hundred parts by weight of the tincture of opium is made up by exhausting ten parts of powdered opium with diluted alcohol. The powder itself to yield not less than twelve or more than sixteen per cent. of morphine when assayed by the prescribed method of assay. Consequently the tincture must contain at the least one tenth of twelve per cent., that, is one per cent. and two tenths of morphine by weight. This is a standard requirement about as definite as language can well express. How different, however, would it be with the latest edition of the United States Dispensatory as the standard. There "one ounce av.," is to be made up into "ten fluid ounces of the tincture." What is here the minimum standard percentage weight of morphine in a tincture which by experience has been found to range in specific gravity all the way from 0.920 + to 0.990 +? No one can assert positively what it is. Even this Dispensatory itself does not attempt to express any definite results, but says that it would be "*about*" or "*nearly*" thus and so. No convictions, as those who are trying to bring about this change well know, could ever be gained upon the charge of having violated any such indefinite standards. But the trouble that would result from the change does not even end here, for the United States Dispensatory as a commentary treats not only upon the last revision of the United States Pharmacopœia, and the one before it, and in like manner upon the British Pharmacopœias, but also in many cases upon the French and German pharmacopœias. Out of such a large selection of standards, more or less indefinite, according to the various pharmacopœias, — for these several foreign pharmacopœias would then become law in Massachusetts, besides many an unofficial formula, — it would become well nigh useless to attempt any enforcement of the law.

This is just the end which is sought for by those who have felt the disadvantage of the present more definite standard. Having rid themselves of this trouble they are very willing that the rest of the act should remain unaffected, as it would have been rendered perfectly harmless against adulterations. No valid reason can be given for the desire to make the commentary the legal superior of that upon which it comments. Surely any private commentary upon a statute is not superior to the statute itself.

— The eighth annual meeting of the New York State Veterinary Society was held at the Ashland House March 11th, with Dr. A. F. Liautard in the chair, when the draft of a bill regulating the practice of veterinary medicine and surgery was discussed and finally referred to the executive committee. Dr. Liautard was reëlected President of the Society.

MEDICAL NOTES.

— Dr. Alfred Hosmer, of Watertown, has resigned his position as one of the medical examiners for Middlesex County. Dr. Julian Mead has been nominated as his successor.

— Dr. Francis M. Gunnell has been appointed Surgeon-General of the Navy. He is a native of Washington and has had thirty-five years of service in the medical corps, nearly half of that time having been spent at sea. The new incumbent is highly spoken of, though it is to be regretted that Surgeon-General Wales, under whom the medical service of the navy had taken such a high position for efficiency, should have failed of reappointment.

— The formula of Tamar Indien, the agreeable and convenient laxative, is announced (Report de Phar., July, 1883) as follows: —

℞ Tamarind pulp	450 parts.
Powdered sugar	40 parts.
Powdered sugar of milk	60 parts.
Pure glycerine	50 parts.
M. Evaporate to consistence of soft extract.	
Add	
Powdered senna leaves	50 parts.
Powdered anise	10 parts.
Essence of lemon	3 parts.
Tartaric acid	3 parts.
M. Divide into 100 boluses. Steam them, and roll in the following mixture: —	
Cream of tartar	5 parts.
White sugar }	āā 35 parts.
Sugar of milk }	
Tragacanth	2 parts.
Tartaric acid	2 parts.
Powdered red sandal	25 parts.
Dry and put up in tin foil.	

— During the past twelve months Dr. John Homans has performed ovariotomy twenty-seven times without a single death.

— An interesting testimony to long-continued, faithful medical service transmitted from sire to son is afforded in this picture drawn by the *Canadian Medical Journal* of a doctor's door: —

"Grandfather, father, and son have been in the old stand so long that to the inhabitants of the locality the doctor's house is amongst the things which have always been. The patients' entrance is on a side street, and a small porch protects the visitor. The steps are well worn, and the native grain is everywhere visible in the wooden surroundings. There is neither bell nor knocker, and the door presents interesting, and, so far as we know, unique evidence that votaries to this Æsculapian shrine have not been lacking. On the panels, at different heights, are three well-worn places where the knuckles of successive generations of callers have rapped and rapped. The lowest of the three, about three feet from the floor, represents the work of 'tiny Tim' and 'little Nell,' so often the messengers in the poorer families. Higher up and of less extent is a second depression where 'Bub' and 'Sis' have pounded, and highest of all, in upper panel, a wider area where the firmer fists of the fathers and brothers have, as the years rolled on, worn away the wood to nearly half its thickness."

In unpleasant contrast with the simple dignity of such a symbol as this of the good physician's home are those doctors' signs which the same journal describes as so common in Canada, the representations of the commercial spirit in medicine. For instance, the writer speaks of metallic door-plates two feet square, with letters five inches high, bearing an inscription like the following: "Dr. ——, M. D., Edinburgh. (Honors) M. R. C. S., Eng., L. A. H., Dublin."

NEW YORK.

— The ninth annual commencement of the American Veterinary College was held at Chickering Hall on the evening of the 4th of March. The graduating class, of which Hamilton Vruland was the valedictorian, numbered twenty-two members, and the address to the class was delivered by the Rev. Dr. John P. Newman.

— The commencement exercises of the New York College of Dentistry were held at the same place on Thursday evening, March 6th, when the valedictory address was delivered by George J. Neish, of the Island of Jamaica, and the address to the graduates by the Rev. Dr. Howard Crosby. The class numbered forty-one.

— A project has been set on foot for the founding of a hospital and clinic for the treatment of cancer cases exclusively. A board of managers, composed of five ladies, five physicians, and five laymen, has been organized, with Mr. John E. Parsons as president, and Mr. Joseph W. Drexel treasurer, and it is said that the sum of $250,000 is already promised for building purposes provided that $100,000 more can be raised for the purchase of suitable land. The five medical members of the board are Drs. Hunter, Cleveland, Kinnicutt, Peabody, and W. T. Bull.

— Dr. Joseph E. Janvrin has been appointed gynæcologist to the New York Skin and Cancer Hospital *vice* Dr. James B. Hunter, resigned.

— The annual commencement exercises of the Medical Department of the University of the City of New York were held at the Academy of Music, Tuesday evening, March 11th, the Rev. Dr. John Hall, Chancellor of the University, presiding. The degree of M. D. was conferred on 164 graduates, and the usual prizes and honors were awarded. The valedictory address was given by F. K. Perkins, and the address to the graduating class by the Hon. Chauncey M. Depew.

— The Bellevue commencement was held at Steinway Hall on the evening of March 13th. The graduating class, of which there was no valedictorian, numbered 149. It was announced that positions upon the house-staff of Bellevue Hospital would be given at once to the four students standing highest in scholarship, and that the next four in order of merit would be appointed on the staff as soon as vacancies should occur. Among the first four was Reginald H. Sayre, younger son of Prof. Lewis A. Sayre. The address to the class was delivered by the Hon. Algernon S. Sullivan.

— The State Board of Health met in New York, instead of Albany, on the 12th of March. The report of a sub-committee appointed to inquire as to the poisonous nature of water gas was received and adopted, but it was announced that its contents would

not be made public until after it had been submitted to the Legislature. By request, Professor Chandler made some remarks on the subject, in the course of which he said that while water gas contained three times as much poisonous carbonic oxide as coal gas, it was practically no more dangerous than the latter. Those asphyxiated by coal gas would die just as surely as the victims of water gas poisoning, although a little longer time would elapse before the fatal result was reached. He believed that the reason why there were more cases of suffocation from water gas than coal gas was simply because in the places where these accidents usually occurred, such as hotels and apartment houses, more water gas was used. Water gas, he said, was now used by half the people in New York, and it furnished fifty per cent. more light than coal gas for the same price. The administration of the food and drug laws was considered and referred to the public analysts, who will agree on a definite plan of action to be submitted to the board for approval. A bill appropriating $20,000 to the board to assist in preventing adulterations is now before the State Senate. Dr. Alfred L. Carroll, of West New Brighton, Staten Island, was elected secretary of the board, in the place of Dr. Elisha Harris, deceased.

— The report of the State Board of Health to the Legislature, in regard to water gas, was made on the 14th of March, and was to the effect that, judging from such investigation as they had been able to make, of the subject, this was not more dangerous or detrimental to health than any other illuminating gas.

— Dr. Whitman V. White has been elected corresponding secretary of the New York County Medical Association. The recording secretary is Dr. E. A. Judson, who was the Old Code candidate for that position at the last election in the County Medical Society.

— Another fat girl, Jessie Reed, died at Buffalo, where she had been on exhibition at Bunnell's Museum, on the 12th of March. She was twenty years old, six feet and four inches in height, and weighed four hundred pounds. She had been married for two years, and leaves one child, six months old. Her remains were brought to Greenpoint, Long Island, where her parents live, and the coffin is said to have measured six feet seven inches in length, thirty inches in width, and eighteen inches in depth.

— Dr. Cyrus Edson, chief of the second sanitary division, having in charge the prevention of adulterations of food, has had a number of samples of mustard, obtained from various dealers, analyzed by Dr. Elwyn Waller, and the result shows that flour is not infrequently used to adulterate pure mustard, while in order to maintain the color of the article a sufficient quantity of what is known as naphtholine yellow is added. This substance is a highly irritant poison, which, when ignited, explodes with almost as much force as gunpowder, and cases against vendors of the adulterated mustard will be prepared by the counsel to the Board of Health.

—The Aqueduct Commissioners, including the Mayor, Controller, and Commissioner of Public Works, accompanied by the chief and consulting engineers, left the city on March 11th to visit Baltimore and Washington, and inspect the water systems of those cities. The last of February Commissioner Thompson, of the Department of Public Works, made his report of the work of the department up to December 31, 1883. In regard to the supplementary Bronx River system, upon which work had been commenced three years ago, he said that rapid progress had been made in carrying out the project, and that by the 1st of September it was expected that 5,000,000 gallons of water per day would be furnished through the conduit and distributed to the Twenty-third and Twenty-fourth Wards; while as the Kensico reservoir and the Rye Ponds became filled by the autumn rains, the supply would gradually be increased to about 10,000,000 gallons per day. In the report it was stated that until a new aqueduct was built, the efficiency of the water service depended entirely on further means and measures to prevent waste. From fifteen to twenty miles of pipes were added each year to the distributing system, and the consumption of water in the built-up portion of the city increased rapidly, in consequence of the erection of large business buildings and apartment-houses. During the last quarter the waste inspectors had made 15,308 house inspections and 9893 night inspections of house-drains, and reported 1770 cases of leaks from defective plumbing and 1614 places were water was wasted between midnight and 6 A. M. at the rate of from one to five gallons per minute.

Miscellany.

THE DISCOVERY OF THE GERM OF SWINE PLAGUE.

Dr. D. E. Salmon, of the Agricultural Department, Washington, published a communication in *Science* [February 8, 1884] upon the discovery of the germ of swine plague, criticising a statement made by Pasteur before the Paris Academy of Sciences last November. In this statement Pasteur, whilst claiming for Thuillier the credit of the discovery of this microbion of *rouget*, recognizes its simultaneous and independent discovery at Chicago by Dr. Detmers. Dr. Salmon claims to have anticipated both these observers by more than a year, and his comments are summed up in the following sentence: —

"It is a matter of record, therefore, that the organism which constitutes the cause of swine plague was first discovered by Klein in 1876, but that he failed to connect it in any way with the virus of the disease, and afterwards concluded that it depended upon a very different schizophyte. It is also a matter of record that I was the first to demonstrate by satisfactory methods that this micrococcus exists in the blood during the life of the animal, that it can be cultivated in flasks, and that the sixth successive cultivation, made in considerable quantities of liquid, and which contained no other form than micrococcus, still produced the disease. Neither Pasteur and Thuillier, nor any other investigators that I am aware of, have added one particle of evidence, except by way of confirmation, to that previ-

ously advanced by me. M. Pasteur is usually very particular in giving credit, but he does not seem to be keeping up with the progress of American science."

PETTIFOGGING BY THE DRUG ADULTERATORS.

THE *Daily Evening Traveller*, of this city, under date of March 17th, comments with well-merited severity upon an indecent circular which has been widely circulated in this vicinity of late in the interest of the manufacturers of adulterated drugs. The circular referred to is a collection of false statements and misrepresentations intended to influence legislative action in the direction of repealing the present statutory restrictions against adulterated drugs. The circular is signed with the name, says the *Traveller*, of "a well-known and influential gentleman who is acting as counsel of certain druggists who are urging some minor amendments of the law, but not its repeal. The name is printed in capital letters, and so placed as to appear to be his signature to the circular, which in point of fact was prepared and printed without his knowledge. This trick, intended to give to the statements of an anonymous circular the apparent authority of a respected and responsible ex-senator, is in complete keeping with the falsehoods and adroit misrepresentations which appear in every line. For example, the Dispensatory is a mere commentary upon the Pharmacopœia, and not the latter upon the former, as stated; and the drug referred to in that connection bore the label U. S. P., to indicate to the purchaser that it was prepared in accordance with the Pharmacopœia. The obnoxious bill and order referred to were not offered with the knowledge or wish of the Board, but are evidently a part of the previous scheme of the authors of the circular, who wish to rally to their aid the owners and venders of proprietary medicines and the opponents of the legal regulation of the practice of pharmacy. It is the opinion of the opponents of adulteration that the cunning attempt to work upon the fears of country druggists and grocers will undoubtedly cause considerable pressure to be brought to bear upon individual members of the Legislature, but that this effect is likely to be more than offset by the insight which the circular will give into the character and motives of the scoundrels who are trying to protect their dishonest gains by crippling the State Board in its vigorous and impartial enforcement of the laws."

HIGH AND LOW CEILINGS.

WE find in the February number of the *Practitioner* an article presenting the opposite views as to the most desirable height for rooms in the average grade of dwelling. On the one hand in a recent report to the Court of Common Council Dr. Sedgwick Saunders raised a protest against the erection, in Petticoat Square, of certain artisans' buildings for the reason that all the rooms above the ground floor are only eight feet in height. He shows by reference to a number of similar buildings that the general average height of rooms in modern blocks for working men is nine feet; that they vary from about ten feet on the ground floor to eight feet seven inches on the fifth and sixth stories; and he urges, on the ground of health, that every room occupied by the working classes should be at least nine feet, and preferably ten feet, in height On the other hand, Mr. John Honeyman recently read a paper before the Congress of the Sanitary Institute at Glasgow, in which he stated that there were distinct advantages in having low ceilings. Mr. Honeyman asserts that where land is dear and the demand for dwelling accommodation great, the builder will naturally be tempted to make stories low, and thus to increase their number, instead of constructing buildings of a few high stories; and that in this way an increased number of tenements can be provided at a reasonable cost, a method of procedure which of all others tends to the prevention of over-crowding. He further asserts that with the appliances which alone are available in the tenement of the working man it is far easier to ventilate a low room than a lofty one; that if a room be low in proportion to its area it will be better ventilated by the fire-place and doorway than if a space of stagnant air be provided at an elevation above the reach of such means of ventilation; and that high rooms mean a wasteful expenditure of money, with consequent increase of rent, which encourages in the most direct manner over-crowding with all its attendant evils. He also states that there is no necessary connection between density of population and a high death-rate, as the statistics compiled concerning the inmates of various improved dwellings show.

Provided a certain cubic capacity per occupant could always be insisted on, it would be better that it should include the comparatively large amount of floor area which would be necessary in the case of a room eight feet in height than that it should be partly contained in the higher strata of a room ten feet in height with a corresponding diminution of floor space. It will probably be found impossible, in the present state of public opinion, to require much more than 400 cubic feet for each adult, and half that amount for children under ten years of age, even in the case of a sleeping apartment which is not exclusively used for that purpose, and this minimum capacity must be regarded as utterly insufficient unless we have along with it a constant and rapid change of air. "But," to quote Mr. Honeyman, "to effect this change so that the whole volume shall be kept up to a safe standard of purity it is necessary that the fresh air should be properly distributed, and permeate the whole apartment. This point, we fear, is sometimes lost sight of. For example, if we take a room of 2000 cubic feet with five inmates, to keep the air, not as pure as we could wish, but in a tolerably healthy condition, at least 5000 cubic feet of fresh air would require to be passed through the room per hour, and as an ordinary open fire will easily attract that quantity there seems to be no great difficulty about it. But observe it is quite possible to pass all that quantity through the room without purifying the atmosphere in any appreciable degree; we may let it all in at one side of the room, and up the chimney at the other, leaving the air breathed by the inmates impure and poisonous, perhaps fatally, so that the more complete the distribution of fresh air the more beneficial will the ventilation be. Now the facility of distribution will depend to a large extent on the form of the room. If the room (always bearing in mind that we are speaking of rooms of the same cubic capacity) be high in proportion to its area, and the fresh air be admitted in the usual way referred to, the lower part only will be ventilated, and a large proportion of its atmosphere will remain impure;

whereas if it be low in proportion to its area it will all be well ventilated, and the inmates will get the full benefit of the room's capacity. In the other case they would not, as a considerable proportion of the high room would remain stagnant and foul, a condition objectionable on other grounds."

Deaths reported 2750 (no reports from Cincinnati and Buffalo): under five years of age, 951: principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 425, consumption 419, lung diseases 397, diphtheria and croup 127, scarlet fever 72, diarrhœal diseases 57, malarial fevers 33, typhoid fever 27, measles 21, puerperal fever 21, erysipelas 19, cerebro-spinal meningitis 19, whooping-cough 17, small-pox 12. From *malarial fevers*, New Orleans 14, New York eight, Brooklyn three, Chicago, Baltimore, and St. Louis two each, Philadelphia and Nashville one each. From *typhoid fever*, Philadelphia nine, New York five, Baltimore four, Pittsburg two, Brooklyn, Chicago, St. Louis, District of Columbia, Milwaukee, Lynn, and Somerville one each. From *measles*, Baltimore 11, New York four, Brooklyn, Chicago, St. Louis, District of Columbia, Providence, and Nashville one each. From *puerperal fever*, Chicago and Boston five each, Brooklyn four, New York three, Philadelphia, Baltimore, St. Louis, and Nashville one each. From *erysipelas* New York six, Philadelphia five, Chicago three, St. Louis two, Milwaukee, Lawrence, and New Bedford one each. From *cerebro-spinal meningitis*, New York six, Chicago and Boston three each, Philadelphia two, Baltimore, New Orleans, Worcester, Chelsea, and Brockton one each From *whooping-cough*, New York nine, Baltimore three, Brooklyn, Chicago, Boston, New Orleans, and Pittsburg one each. From *small-pox*, New Orleans ten, Philadelphia and Nashville one each.

Five cases of small-pox were reported in St. Louis; scarlet fever 48, diphtheria 22, and typhoid fever nine in Boston; scarlet fever six and diphtheria three in Milwaukee.

In 87 cities and towns of Massachusetts, with an estimated population of 1,321,530 (estimated population of the State 1,955,104), the total death-rate for the week was 20.30 against 18.00 and 16.72 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending February 23d, the death-rate was 21.1. Deaths reported 3538: acute diseases of the respiratory organs (London) 345, whooping-cough 127, scarlet fever 99, measles 95, diarrhœal diseases 38, fever 34, diphtheria 29, small-pox (London four, Birmingham three, Sunderland two, Liverpool and Newcastle one each) 11. The death-rates ranged from 14.1 in Portsmouth to 28.1 in Manchester; Leicester 16.9; Bristol 17.2; Bradford 18.2; Birmingham 18.6; Sheffield 19.8; London 20.2; Birkenhead 20.7; Liverpool 23.9: Newcastle-on-Tyne 25.9; Leeds 26.8; Nottingham 26.9. In Edinburgh 23.1; Glasgow 25; Dublin 30.

For the week ending February 23d, in the Swiss towns, there were 29 deaths from lung diseases, consumption 23, diarrhœal diseases 19, diphtheria and croup 10, whooping-cough six, typhoid fever five, measles, scarlet fever, erysipelas, and puerperal fever each one. The death-rates were, at Geneva 23.4; Zurich 11.8; Basle 20.1; Berne 25.6.

The meteorological record for the week ending March 8th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

RESOLUTIONS OF THE BERKSHIRE DISTRICT MEDICAL SOCIETY ON THE DEATH OF DR. ALMON N. ALLEN AND DR. H. L. SABIN.

AT the regular monthly meeting of the Berkshire District Medical Society the following resolutions were adopted: —

Whereas, Our brother, Almon N. Allen, of Pittsfield, has been removed from the scene of his long and useful labors on earth, and, as we trust, to a happy and everlasting home in the life which succeeds this; therefore —

Resolved, That while we bear our willing testimony to his character as a man and a physician, and deplore his absence from this our monthly meeting of the Society, we tender to his wife, son, and other relatives the sincere expression of our condolence and sympathy in their affliction, and commend them to the love of that Being "who doeth all things well."

Resolved, That a copy of these resolutions be forwarded to the family of our deceased brother, *The Boston Medical and Surgical Journal*, and the same be sent to the Berkshire County *Eagle*, and Pittsfield *Sun* for publication.

Resolved, That a copy be placed on the records of this Society.

A. M. SMITH,
F. K. PADDOCK, } Committee.
O. S. ROBERTS,

Whereas, Our beloved brother, Dr. H. L. Sabin, of blessed memory, has been removed from our association,

Resolved, That we cherish with lively gratitude his long and happy union with us; we shall ever remember and be stimulated by his devotion to and love for his profession; his uniform kindness and courtesy; his eminent ability; his scrupulous adherence to high professional integrity; his hatred of shams; his just appreciation of noble purpose and endeavor; his manly eloquence in the cause he considered pure and just, and his Christian firmness and gentleness.

Resolved, That while we cannot mourn for the happy termination of such a long, useful, and noble life, yet we tender to his family our sincere sympathy in this bereavement.

Resolved, That these resolutions be sent to the family by the Secretary, spread upon the records of this Society, and published in *The Boston Medical and Surgical Journal*.

T. K. DEWOLF,
C. L. HUBBELL,
N. S. BABBITT, } Committee on the above Resolutions.
A. M. SMITH,

H. COLT, JR., *Secretary Berkshire District Medical Society.*

OFFICIAL LIST OF CHANGES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MARCH 8, 1884, TO MARCH 14, 1884.

BILLINGS, JOHN S., major and surgeon. Granted leave of absence for one month, with permission to go beyond sea, to take effect April 1, 1884. Paragraph 6, S. O. 61, A. G. O., March 13, 1884.

HEIZMANN, CHARLES L., captain and assistant surgeon. Leave of absence extended three months. Paragraph 9, S. O. 57, A. G. O., March 8, 1884.

WALES, PHILIP G. Appointed to be assistant surgeon, with the rank of first lieutenant, to date from February 7, 1884, vice Brewster, resigned. Mem. A. G. O., March 10, 1884.

FISHER, WALTER W. R., and POLHEIMER, ADRIAN S., first lieutenants and assistant surgeons, assigned to duty in Department of California.

STEPHENSON, WILLIAM, BORDEN, WILLIAM C., and CHAPIN, ALONZO R., first lieutenants and assistant surgeons. Assigned to duty in Department of the Platte.

ROBERTSON, REUBEN L., and EDIE, GUY L., first lieutenants and assistant surgeons. Assigned to duty in Department of Texas.

CROSBY, WILLIAM D., first lieutenant and assistant surgeon. Assigned to duty in Department of Arizona.

GANDY, CHARLES M., first lieutenant and assistant surgeon. Assigned to duty in Department of East.

PILCHER, JAMES E., first lieutenant and assistant surgeon. Assigned to duty in Department of Dakota. Paragraph 4, S. O. 55, A. G. O., March 6, 1884.

KNEEDLER, WILLIAM L, first lieutenant and assistant surgeon. Assigned to temporary duty at Fort A. Lincoln, D. T. Paragraph 3, S. O. 26, headquarters Department of Dakota, March 8, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE TWO WEEKS ENDING MARCH 15, 1884.

AMES, H. E., passed assistant surgeon, from the Colorado and ordered to the Greely relief steamer Bear.

TERRILL, F. H., passed assistant surgeon, to coast survey steamer Hassler.

MCCARTHY, R. H., passed assistant surgeon, from the coast survey steamer Hassler and wait orders.

DEATH, — Died, at Longmeadow, Mass., March 14, 1884, George Hooker, M. D., M. M. S. S.

APPOINTMENT. — Everett Torrey, Esq., has been appointed a member of the Massachusetts Board of Health, Lunacy, and Charity, in place of Hon. Thomas Talbot, retired.

BOOKS AND PAMPHLETS RECEIVED. — The Veins of the Brain and its Envelopes. Their Anatomy and Bearing on the Intra-Cranial Circulation. By William Browning, M. D., Brooklyn, N. Y. Brooklyn, N. Y.: F. B. O'Connor, Jr., 68 and 70 Court Street. 1884.

Minutes of a Convention held in the City of Albany, February 4 and 6, 1884, at which the New York State Medical Association was Organized on a Permanent Basis.

Report of the Secretary of the State Board of Health of West Virginia for the Years ending December 31, 1881, 1882, and 1883. Wheeling. 1884.

Fifteenth Annual Report of the Trustees of the Willard Asylum for the Insane to the Legislature. For the Year 1883. Albany. 1884.

Original Articles.

PREVESICAL CELLULITIS FOLLOWING HERNIOTOMY. PHLEGMONOUS ABSCESS, "SOUS-OMBILICALE," IN HEURTAUX SPACE.[1] PERINEPHRITIC ABSCESS.[2]

THREE CASES REPORTED BY WILLIAM INGALLS, M. D. (HARV.)

CASE I. PREVESICAL CELLULITIS, FOLLOWING AN OPERATION FOR STRANGULATED HERNIA.

P. H., Irish laborer, age twenty-two years, single, was admitted to the Boston City Hospital on the 28th of April, 1883, having right inguinal hernia which occurred five years previously, after a fall from a height, and which has troubled him ever since, but which he has always been able to "put up" on its coming down until the 24th, when it came down, and his usual efforts to reduce it were ineffectual. During these last four days the patient has suffered great pain in the abdomen and some nausea, but no vomiting until yesterday when he took some medicine. After reduction by incision, sutures, drainage tube, Lister dressing. There was restlessness in the night, but neither vomiting nor chill; some pain and tympanites also, which were modified by morphia; on the 30th there was increased tympanites.

May 1st. Abdominal tenderness less.

May 7th. The wound is granulating; there is complaint of pain in hypogastrium and difficult micturition; and up to the 15th there continued to be abdominal pains and tenderness; diarrhœa; also a development of induration, pre- and supra-pubic, the area of which was a little more extensive on the right side than on the left; it was circumscribed. These symptoms led to an examination by the rectum, and there was found to be considerable tumefaction and induration in the prostatic region, recognition of the prostate gland being obscure. Analysis of the urine: specific gravity 1027; color normal; reaction acid; albumen one per cent. The wound is doing well.

May 15th. At this date the diagnosis was "a forming prevesical abscess."

From this date the tumefaction by degrees subsided, the wound healed rapidly, all the symptoms disappeared, and the patient was discharged, well, on the 11th of June, forty-eight days after the strangulation. There was at no time fluctuation of the prevesical tumor, nor was there any discharge therefrom.

CASE II. PHLEGMONOUS ABSCESS OF ABDOMINAL WALL.

D. L., 'longshoreman, age thirty-nine, Englishman, on the 11th May last was presented on the operating table for examination, not having previously been seen by myself. The history of the case is that up to about two weeks ago he had been generally in good health; that about that time he noticed a small bunch a little below the umbilicus which began to grow, with increasing pain on pressure and also upon coughing. Micturition became difficult and painful, and "there was a sensation as of a weight pressing upon the bladder."

Inspection discovered a tumor of the form of a demi-ellipse, the base of which was a horizontal line drawn across the umbilicus, the apex below, the diameters fully four inches, and the prominence, perhaps, an inch higher than the normal surface, red and fluctuating. Without ether the abscess was incised, and a large amount of pus poured forth, a number of clots of broken-down tissue being mingled therewith. The man was discharged in good condition with the wound closed on the 3d July, fifty-four days from operation, sixty-eight days from first notice of pain.

CASE III. PERINEPHRITIC ABSCESS.

A. C. S., age twenty-seven, Bostonian, workman in a shoe factory, entered hospital May 10, 1883, and reports that ten days ago he had pain in left abdomen, and he indicated a spot an inch below the point of the lowest rib at which a swelling or fullness was simultaneously felt, and which increased, as also did the pain.

Examination proved the existence of a circumscribed swelling at the region indicated, fluctuating and painful on pressure. This was incised and a large amount of pus escaped. Drainage tube and usual dressing.

June 5th. Twenty-six days from the above-mentioned opening, which has healed. The case has been going on well for the most part, but there has been some complaint of pain in left lumbar region, and there is now some pain shooting down the side and lower limb; the complexion is pale, and there is an anxious expression of face.

June 8th. A fullness over left kidney in process of formation during these past three days induced a suspicion of a forming abscess, and was to-day found to have ripened into one, and from this, upon its being opened, there flowed a large quantity of pus.

On the 11th of July, health and strength being much improved by suitable tonics and moderate exercise out of doors, he was discharged, well.

The position of the first abscess was front of, and precisely opposite to, the junction of the lower and middle third of the kidney, perhaps a little lower, and it is an afterthought that it was a perinephritic abscess, for it seems to be an unusual site for the pointing of one.

In a majority of cases pain in the side and pain shooting down the lower limb are complained of during the formation of the abscess; these symptoms were not alluded to by the patient until the forming of the second abscess. Although the kidney is not diseased in all cases of perinephritic abscess, yet the urine in all cases should be examined; it was not examined in this case, and the omission is inexcusable.

In the *Annals of Anatomy and Surgery* for December, 1882, there is an article by Dr. Pilcher entitled Prevesical Phlegmons.

He says: "The slight attention which has been paid to the study of phlegmons and abscesses, especially when considered from a topographical point of view, is very notable; . . . among the 182 monographs enumerated by title upon the subject of abscesses, including phlegmons and cellulitis, 102 are French, fifty Latin, nine English, two American, and nineteen from other nationalities."

Dr. Pilcher's paper is full, and, as the reader thinks, admirable as to the regional anatomy and the position and the causes of the subject in hand; as all may read, it is not expedient to be too free with extracts; but his "Conclusion" may be permissible, as follows:—

"Submuscular phlegmons are the result of bloody effusions upon the posterior face of the recti muscles,

[1] Bulletins et Memoires de la Société de Chirurgie de Paris, tome iii., page 611. Phlegmon sous-ombilical, par le Dr. A. Heurtaux.

[2] Read before the Surgical Section of the Suffolk District Medical Society, January 2, 1884.

and the prevesical phlegmons are the consequence of an affection of some of the organs contained in the true pelvis. Submuscular phlegmons develop from the pubes towards the umbilicus . . . and have no prolongation into the true pelvis.

"The prevesical phlegmons form tumors which, situated in the true pelvis, and consequently accessible to rectal touch, rise more or less above the pubes, between it and the bladder, and may extend towards the rectum and the iliac fossa. . . . Resolution is rare."

It seems to the writer that he is justified in believing that the first case was a cellulitis beginning in the cavity — properly, *space* — of Retzius, for, first, there was "an affection of some of the organs contained in the true pelvis," namely, the yet unhealed herniotomy; second, the swelled and hard prostatic region; third, the formation of a hard plate which formed in front of and above the pubes; suppurative action did not take place, else there would have been a typical prevesical abscess instead of, or a result of, the cellulitis.

The second case is a submuscular phlegmon such as is described and delineated by Castaneda y Campos,[1] as "Le phlegmon sous-ombilicale," and these do not invade the precincts of the true pelvis.

It may be said at this point that there is, apparently, good reason why results of study of this subject *as regional disease* have not been published in this country; for having searched the records of the Boston City Hospital from 1870 to the present time no record of anything of the kind was found; moreover, the records of the Massachusetts General Hospital for the years 1877, 1878, 1879 were thoroughly searched, and but one case bearing upon the subject was found. Therefore, it may be presumed, justly, that cases of the kind under consideration are rare, at all events, in this part of the country.

When the case of sub-umbilical abscess was uncovered for examination, Dr. Fifield being present immediately recognized it as a disease described by several French authors, and in connection with it called attention to the fact that this and prevesical abscesses were in near relationship for purposes of anatomical consideration.

A CASE OF CYSTO-PYELITIS OR PYELO-CYSTITIS OR CYSTITIS COINCIDENT WITH PYELITIS.[2]

BY EDWARD O. OTIS, M. D.

I FIND myself in the rather anomalous position of presenting a case of which I seem to have about as many suppositions as to its exact diagnosis as existed with regard to the mental condition of Hamlet. Still the case has seemed to me one so suggestive in so many of its aspects and so shrouded in doubt as to its exact nature and origin that I have ventured to report it. It extended from May, 1881, to June, 1883.

H. R., a midshipman, twenty-two years of age, of phthisical parents, enjoyed robust health while at the naval academy, and for two years after while on a cruise to the West Indies and northward. He sustained successfully all the physical examinations required from time to time while at the naval academy and in the service. In the latter part of May, 1881, some months after the expiration of his cruise, he went to Annapolis to pass his examinations for promotion. He studied hard and late, and while there played a game of base ball in which, after being heated, he sat down on the ground, but with no apparent evil result. I believe he was also hit by a ball in the bladder or genital region somewhere, but of this I cannot be sure; if he was it was not severe enough to make any lasting impression upon him, so that I do not think he mentioned the fact to me. The medical officers under whose care he subsequently came also had the impression that he received such a blow, but I find no mention of it in their records. A short time after this game he began to feel a slight trouble in the bladder region while walking and while urinating. This continued five weeks before any physician was consulted, and all this time he was about, the last act before taking to his bed being to walk six or seven miles. The pain increasing he consulted an eminent surgeon, who said he had all the symptoms of stone, and sounded for it at two different times with negative results. He was given a prescription for cystitis composed of pareira brava, liq. potass., etc. The pain referred to the perinæum and head of the penis increased so that he took to his bed. He was visited once at his house by the same surgeon, who washed out the bladder, and also made an examination of the urine, the result of which I obtained through his kindness, and which was as follows: Reaction acid; specific gravity 1020; albumen, one eighth of one per cent.; large amount of pus and mucus; bladder epithelium; a few blood corpuscles.

I saw him for the first time September 14, 1881. He was passing his water about every two hours, and complained of pain, which he located two or three inches from the head of the penis. There was no tenderness over the region of the bladder or in the lumbar region. No tenderness or enlargement of the prostate. He was obliged to keep the dorsal decubitus now, as all through his illness, on account of the pain when he attempted to lie on his side. The other organs were healthy with the exception of a mitral systolic souffle. My examination of the urine was practically the same as the one previously made. I did not take the temperature at that time, but three or four days later it was 102.8° F., and continued to vacillate from this time on between normal and 104° F. My treatment was essentially that instituted by his previous physician; the prescription above referred to was continued, also decoction of triticum repens and a weak alkali, and the bladder was washed out gently sometimes with simple warm water, sometimes an astringent or antiseptic was added to the water. Other symptoms, digestive derangements, fever, pain, etc., were treated according to the indications. September 19th he complained of *pain in* the *right loin*, and the following day pain just below the cardiac region. September 21st the pain in the right loin had *disappeared*. November 8th the note is made that he complained of soreness and pain in the *right iliac* region. From the time I first saw the case until November 14th, when he entered the Naval Hospital at Chelsea, the course of the disease was one of great variations, — now a chill and high fever and profuse perspiration, with gastric disturbance, pain, and much depression; now absence of all fever and pain, fair appetite, and general well being. The urine also varied much as to its abnormal ingredients, and as to the intervals between passing it.

[1] Du phlegmon, etc., page 88.

[2] Read before the Surgical Section of the Suffolk District Medical Society, January 2, 1884.

At one time he passed several clots, and there was much blood. The last examination which I made, November 7th, was as follows: specific gravity 1016; reaction neutral or slightly acid; albumen, from one half to one per cent.; abundance of pus; few blood corpuscles; amorphous matter.

From November 14, 1881, to June 19, 1883, when he died, he remained at the Chelsea Naval Hospital, and for the record of his case while there and an account of the autopsy I am indebted to the surgeons on duty there during this period, and especially to Dr. A. C. Gorgas, Medical Inspector United States Navy. During this time the disease progressed steadily, but with short intervals of remission, when all the general symptoms would be much improved, with diminution of pus in the urine. There was usually rise of temperature in the afternoon, and almost continual pain, so that finally he became an opium eater in consequence, with all the train of symptoms such as is consequent upon a chronic suppurating disease. The bowels were generally obstinately constipated, and evacuated with much pain and depression. The urine, I believe, was always acid, often so strongly that an alkali had to be exhibited. At no time could he lie on either side. There was pain at times in the right lumbar region, but not constant, neither was there any marked tumor there. A very noticeable and significant symptom was the extreme constipation and flatulence, caused, undoubtedly, by adhesions about the intestines, preventing peristalsis and permitting gaseous collections. The remedies tried were innumerable, none of which apparently exercised any influence over the course of the disease, copaiba, sandal-wood oil, iron, alkalies, diuretics and astringents of different kinds, sedatives and tonics. The bladder was also washed out with various medicated waters containing antiseptics and astringents. In order to represent the progress of the disease more vividly I will give extracts from the record of the case after he left my care: —

November 17, 1881. Patient cannot stand or walk without much pain, or lie on either side.

December 22d. Urine examined: acid; large amount of sediment, pus and mucus corpuscles, occasionally a blood globule. Pain and tenderness over membranous and prostatic portions of urethra. No particular sensitiveness over either kidney nor in hypogastrium. Temperature in morning normal, in evening 101° F. to 102° F.

December 30th. Movement of bowels always causes pain.

January 14, 1882. Retains urine from six to eight hours. Freedom from pain. Ability to move about. Much less amount of pus and mucus. [Taking opium daily.]

February 20th. Seat of pain at membranous and prostatic portion of urethra and neck of bladder. Urine much increased. Pus less than a month ago.

May 14th. Decided and well-marked tenderness over parts corresponding to *left kidney*, and pain starting from that point and following course of ureter to bladder and penis.

May 15th. Pain over left kidney relieved. Urine and pus tinged with blood. No casts or renal epithelium. Reaction acid. Occasional night sweats.

May 16th. More blood in the urine; color that of port wine. Crystals of oxalate of lime.

May 17th. Passage of bowels with much pain and vesical tenesmus. Much blood in the urine. No pain over kidney, as before.

May 18th. Violent paroxysm of tenesmus and pain starting from neck of bladder and running to end of penis.

June 12th. A sound was passed, but the range of motion found very limited.

June 25th. Condition essentially the same. Neuralgic pains about bladder, penis, and perinæum. Occasional small blood clots. Urine tinged with blood, which has a fresh appearance, as if from bladder wall. Appetite poor.

August 1st. In *right* lumbar region of abdomen a circumscribed hardness is perceptible on percussion and palpation; not very sensitive, but rather sharp pressure producing a painful sensation, referred to deeper parts not distinctly located by patient. The nature or origin of this tumor cannot distinctly be made out, but it lies nearly over the situation of the right kidney. Examination of side and back in same region discovers no marked tenderness nor any tumor.

September 20th. Decided decrease in amount of pus within the last month, and a nearly corresponding decrease of pain.

October 8th. It seems probable that there may be a filling up and temporary emptying of some cavity of pus, whether or not in the kidney. The temperature rises as pus diminishes and falls with its reappearance.

November 13th. Passed several small concretions with a large quantity of pus.

December 7th. Felt a tumor in the right side, which gave much the sense of the liver but that it seemed in a degree globular and gradually sank.

December 14th. Acute pain along the urethra. Urine very pale, but highly acid; deposited about one fifth volume of pus and very great percentage of mucus. Pain so severe took 0.50 gramme of opium and 0.032 grammes of morphine, besides nine grammes bromide potash.

December 17th. Every attempt at micturition accompanied by more or less acute pain and frequent stoppage.

December 22d. Appetite remarkably good.

December 29th. Urine very mildly acid from continued doses of bicarbonate of soda.

January 3, 1883. Inflation of the intestines by gas remains the most embarrassing condition.

January 8th. Right testicle and cord sensitive.

January 16th. Catheter introduced, but produced such pain it had to be withdrawn.

February 5th. Pus less; general condition improved; urinary fluid more natural in color.

February 9th. No nephritic symptoms observed for some time, all pain being confined to urethral, perineal, and supra-pubic parts. Frequently the urine is voided without the least discomfort.

February 16th. Acute cystitis reappeared, with considerable strangury and increase in purulent sediment. [Deprived for the most part of his opium.]

February 21st. Complains of want of relief produced by evacuation of the bowels, a condition due to pressure upon the rectal walls by the thickened and weighty bladder.

March 9th. Diarrhœa and profuse sweating.

March 19th. Attempt made to explore bladder; passage of instrument interrupted at prostatic portion. Upon introduction of finger in rectum the tissues between it and rectum were found to be reduced to such tenuity that neither the use of the least pressure or a smaller instrument than No. 6 was deemed advisable.

March 29th. About 900 cubic centimetres of urine passed daily.

April 14th. Urine contains increased amount of pus.

April 28th. Hacking cough.

May 15th. Dull pain in left chest.

May 22d. Abundant râles heard over left lung. Painful inspiration. Glands of left axilla are enlarged and tender. Pain about articulation of jaws. Increasing emaciation. Urine more abundant. Less pus.

May 27th. But little respiration heard over left lung.

June 16th. Acute pain in right lumbar region, which quickly spread over the abdomen, with marked tenderness. Great distress and prostration. Symptoms of peritonitis. Concentrated urine. Retraction of penis and testes.

June 18th. Frequent vomiting of dark watery fluid, which is apparently altered exudation into the stomach, and independent of ingesta. Respiration oppressed. Circulation more feeble.

June 19th. Dissolution.

Autopsy. Eleven hours after death. Body extremely emaciated. Rigor mortis developed and subsided rapidly; entirely disappeared at time of examination. Brain not examined.

Thorax. Costal pleuræ adherent to chest walls by numerous and strong bands; also to pericardium on left and diaphragm on right side. Inferior portion of upper left lobe of lung consolidated, section sinking in water. Apex congested, bound by adhesions, and the seat of several small vomicæ and cysts of cheesy matter. Upper lobe of right lung also congested, and contained several superficial hard masses, sacs filled with cheesy substance. General pulmonary tissue very pale, but crepitant. Thoracic cavity sensibly encroached upon by abdominal organs. Pericardium contained small quantity of fluid. Heart rather small. Right side filled with clotted blood; and after dividing the aorta a fibrinous clot was withdrawn about twelve inches long, bifurcated, and corresponding with arterial divisions. Similar clots were found in left side. Semilunar valves normal. Mitral found to be insufficient.

Abdomen. A large quantity of sero-purulent fluid in peritoneal cavity, the pus apparently yielded by an abscess resting on the right side of the vertebral column and under lower extremity of kidney, and which was cut into before its discovery. Extensive adhesions between lower abdominal wall and diaphragm. Intestines united with each other, with posterior abdominal wall and omentum by numerous adhesive bands. Omentum studded with adhesive deposit. Stomach contained dark fluid, similar to that vomited, and distended by gas. Intestines congested, and generally attenuated, cæcum containing hard fæcal masses. Descending colon bound down to posterior wall of abdomen, and contracted to one fifth or one sixth its normal calibre throughout its extent; also the rectum. Left kidney normal. The right enormously distended by pus, after evacuation of which it measured six and one half inches in length and four and one half in width, and its medullary structure was found completely destroyed by suppuration, a distinct abscess occupying each pyramidal section. The intervening cellular tissue was thickened into dense septa, and the capsule was greatly hypertrophied. Right ureter occluded. Bladder empty, shrunken, walls thickened, but showing no evidence of recent inflammatory action.

The points of interest in the case seemed to me to be the following: —

I. The insufficient cause. There was no vesical or renal calculus or any injury or exposure which would seem sufficient to give rise to such severe trouble, especially in a young man perfectly strong and robust up to the time of his illness. (I could never find any evidence of venereal trouble.)

II. The origin of the disease. Was it in the bladder or in the pelvis of the right kidney? If a primary pyelitis, why then did we not have pain more constant and confined to the diseased kidney? The first notice of pain in either kidney region was two or three months after the beginning of the disease, and this disappeared in a day or two. The next record of any pain is some six months afterwards, and that in the left kidney. Then, again, a number of months later pain is noticed in the right kidney with some evidence of a tumor. It will be also noticed that the urine was always acid, and often strongly so. The grave constitutional disturbance from the beginning would favor a primary pyelitis, or a very rapid invasion of the kidney if cystitis was the primary affection. Moreover, if cystitis was the original disease why were not both kidneys invaded? I must confess my inability to locate the origin of the disease as well as to ascribe it to any sufficient cause. I would suggest tuberculosis as possible. That there was a pyelo-nephritis in the later part of the disease, with symptoms of pyæmia, there can be hardly any doubt.

We have three suppositions as to its origin: First, it was a case of cystitis from unknown cause, with subsequent extension of the disease to the right kidney. Second, we have a primary pyelitis, also of unknown cause, with later inflammation of the bladder. Or third, we have pyelitis with coincident inflammation of the bladder.

III. As to treatment. Would any surgical interference have been justifiable or advisable? Two operations it seems to me are to be thought of: —

First, one referred to the right kidney. An exploratory incision, or at least an exploratory puncture, with an aspirating needle. But were there indications enough to warrant this? It was not until more than a year after the beginning of the disease that the evidence was sufficient to make it pretty certain that there was suppuration going on in the right kidney, with the formation of an abscess. On August 1, 1882, a circumscribed hardness in the right lumbar region was detected, and later, in December 7th, the note was made that a tumor was felt in the right side, but apparently it could not be very definitely made out. With this evidence and at this advanced stage of the disease would an operation such as I have suggested have been justifiable?

Second. From the symptoms of stone which were present, and also from the doubt as to the origin of the disease, there being at least an equal chance that the bladder was primarily affected, should, in the early days of the disease, an exploratory perineal incision, as suggested by Sir Henry Thompson recently, have been advised? Sir Henry Thompson claims that the operation is simple and easy, and that it is the most valuable aid to diagnosis in cases of obscure bladder trouble; and moreover declares that digital exploration of the bladder can be performed without much risk to

the patient. Further, if the case on perineal section had seemed to be one of pure cystitis, then the section could have been utilized as a remedial measure, as suggested by Dr. Weir, of New York, in the *Medical Record* for June 12, 1880, page 659, by giving free and easy drainage to the organ, and a better and more perfect channel for irrigation.

IV. The difficulty of determining from whence the purulent discharge proceeded. I believe that it is not certain that the epithelial cells of the pelvis of the kidney are characteristic, and if they are, they are not always present or detected. Moreover, the urine is not always alkaline in a chronic case of cystitis of a high grade.

A CASE OF FACE PRESENTATION WITH SOME REMARKS ON THE TREATMENT OF THIS CLASS OF CASES.[1]

BY J. B. SWIFT, M. D.

AT a meeting of this Section last year Dr. Harlow reported a series of twelve cases of face presentation, and showed that the labor might be easier for the mother and safer for the child by an early rectification of the position.

I have recently had a case which I succeeded in converting from face into a vertex, and which I think may be of interest in exciting a discussion as to the proper treatment of these cases.

On the morning of September 9, 1883, about nine o'clock, I was called to attend Mrs. O'D., and on my arrival found her in labor with her fifth child. She says her previous labors have always been tedious and slow, and from the last she was a long time in getting up. She has been married seven years, and is of a decidedly nervous temperament.

Her pains began about two A. M., and although not very severe nor frequent she has had no sleep since they began. Examination per vaginam showed the cervix entirely obliterated, the os open so as to admit the finger, the membranes intact, head presenting, and the anterior fontanelle directly over the os. The head was movable above the brim and could be easily turned over so as to make O. R. P., but it would not remain so. The patient was dressed and about the room, and had eaten her breakfast as usual.

At eleven A. M. there had been no change, and she had had no pains since the first examination. She was advised to lie down and try to get some sleep, taking, if necessary, one drachm of bromidia, which had been prescribed by her regular attendant, and found to act well at times when she suffered from insomnia.

At two P. M. I found that she had slept somewhat without the aid of the medicine, and that the pains had returned, the os being somewhat more dilated than at the previous examination. The head remained in the same position.

At three o'clock I found the os about three quarters dilated and the pains changing in character, becoming expulsive. The head had become more extended, the orbit now occupying a position in the centre of the superior strait. The head was still movable, but pressure on the forehead would now only turn the head so as to bring the anterior fontanelle into its original position. I intended to wait until the os was more fully dilated and then introducing the hand rupture the membranes and bring down the occiput, hoping that with the escape of the waters the head would remain flexed. Unfortunately with the next pain the membranes ruptured spontaneously, and I found the head fully extended, the nose being in the centre of the strait. Pressure on the chin would still convert it into a brow, but the head would turn no farther. I informed the husband of the condition of affairs, and explained to him that I intended to give the woman ether and try to rectify the position. He asked that Dr. F. Minot, who had seen her in one or two of her previous confinements be called in consultation. On his arrival I told him what I proposed doing, and he agreed to the proposition.

The patient was etherized, and introducing my left hand I grasped the occiput, drawing it down into the pelvic cavity and placing it in the right anterior position.

It was deemed advisable to finish the delivery then, rather than leave it to the natural efforts, so the forceps were applied and a female child was extracted. After the delivery of the placenta there was some hæmorrhage, which was controlled by a hot water douche. The woman made an easy and rapid convalescence, the temperature never going above 99° F.

We are told in our obstetric books that the older accoucheurs believed spontaneous delivery by the face to be impossible, and that they always terminated such cases by version. Playfair says: "Smellie first recognized the fact that spontaneous delivery is possible, and that the chin turns forward and under the pubes; but it was not until long after his time, and chiefly after the appearance of Mme. Lachapelle's essay on the subject, that the fact that most cases could be naturally delivered was fully admitted and acted upon."

Such being the case, version was given up and the cases were left to the natural efforts; but it was soon found that these cases were long and tedious, and the prognosis for both mother and child was more unfavorable than in cases where the vertex presented; thus Cazeaux says: "We must remark that, as a general rule, the labor is more tedious, more painful, and more dangerous, both to the mother and child, and that it much oftener demands the intervention of art." According to Winckel the mortality of the children amounted to thirteen per cent., while that of the mothers reached as high as six per cent. Playfair says: "As regards the mother, in the great majority of cases the prognosis is favorable, although the labor is apt to be prolonged, and she is therefore more exposed to the dangers attending tedious delivery. As regards the child, the prognosis is much more unfavorable than in vertex presentations. Even when the anterior rotation of the chin takes place in the natural way it is estimated that one out of ten children is still-born; while if not, the death of the child may almost certainly be expected."

Schroeder says: "The prognosis in face presentations, even with the usual mechanism, is far more unfavorable than in head presentation. While in the latter nearly five per cent. of the children are still-born, that proportion rises to thirteen per cent. in face presentations. For the mother, also, face presentations are more unfavorable than head presentations, because on an average the labor lasts much longer. Of course, the

[1] Read before the Section for Obstetrics and Gynæcology of the Suffolk District Medical Society, November 21, 1883.

prognosis is still more unfavorable if the mechanism is abnormal, that is, when the chin does not take its forward turn. Then scarcely a child will be born alive." And finally Lusk: "Though spontaneous delivery is the rule in face presentations, the dangers to both mother and child are considerably greater than in vertex presentations."

In spite of this unfavorable prognosis we are told to leave these cases to nature, only interfering when it becomes evident that the child cannot be born while in this position. Then, if the head is still movable at the brim, or can be pushed up, there are two methods to be applied: (1) pressure on the chin in such a direction as to cause the head to revolve on its transverse axis; or (2), drawing down the occiput by the hand or vectis introduced into the uterus. These measures failing, or if the head is so firmly fixed in the cavity that it cannot be pushed back, the forceps must be used.

Schatz has proposed a method, by external manipulation, which is to be employed early in the labor. I have not seen the original article, but Lusk speaks of it, though he does not say with what success its employment has been attended. The operation consists in restoring the child to the normal attitude by pressing on the chest in one direction, while with the other hand the breech is pressed in the contrary direction, this having the effect of raising the head and at the same time doubling the child up, when the head will resume its normal position, and the vertex will present. There can be no question that, if this can be done, it should be tried in all cases where the diagnosis is made early, and I regret that it was not attempted in the case which has been reported, but had it been attempted I think it somewhat doubtful whether it would have been successful, for, although when the extension of the head was first discovered it could be corrected by pressure on the forehead, it would not remain so when the pressure was removed. So in any case, although we might be able by this method to remedy the malposition, still the causes which acted originally in making the face present probably would remain, and there is no certainty that the head would stay in its proper position if put there.

The question then arises whether or not in such cases we are justified in going still farther. It seems to me that we are, especially when we take into consideration the unfavorable prognosis to both mother and child, and the fact that it is much easier to rectify all malpositions early than when labor has been going on for some time. Still I would not lay this down as an absolute rule to be followed in all cases, but my plan of treatment would be in all cases to attempt to rectify the position by Schatz's method. If successful, well and good; but if the malposition returns after being rectified, or not being successful in our attempts at rectification, watch the dilatation of the os closely, care being taken not to rupture the membranes; and when the os is sufficiently dilated correct the position by pressure on the forehead, rupture the membranes, and keep up the pressure until the pains have caused the vertex to engage in the brim, when the case, if otherwise all right, can be left to nature. Or if on our first examination we find the membranes ruptured and the head still above the brim, try to correct it by pressure in the manner already described, or, not being able to do this, introduce the hand, grasp the occiput, and bring it down. There are cases, no doubt, in which the pelvis is roomy or the head small, where the face will engage easily and come through the pelvis without much more effort than in a great many vertex cases, but I think it will be found in the large majority of face cases that this is not the rule. The dimensions of the presenting part cannot be reduced in the way they are when the vertex presents, for the bones of the face are united, and will not overlap as the parietals will, therefore a greater exertion is required to force the face through, thus causing a tedious and harder labor, with the risk of tiring out the patient. Another thing to be thought of is the appearance which the child presents after being born in this way. The swelling known as the caput succedaneum of course forms on the face, and Playfair says of this: "Even when the child is born alive the face is almost always greatly swollen and disfigured. In some cases the deformity produced in this way is excessive, and the features are often scarcely recognizable." In spite of our assurance that this disfiguration will all pass away in a few days it must produce rather an unpleasant sensation, to say the least, to present such a child to a woman who has just passed through such an amount of suffering. Probably no one would object to the employment of Schatz's method.

In speaking of the other methods Lusk says: "Though occasionally successful they have been discountenanced by most obstetric writers, because experience has shown the results to be by no means commensurate with the dangers incurred." But he does not tell us what these dangers are. Further along, however, in speaking of the treatment necessary for cases which have been left to nature, and where she has failed, he shows how much more the danger is increased to the woman, and the child is almost always dead.

Playfair argues against interference on the ground that most men are not skillful enough, and then goes on to say in the next sentence: "When once the face has descended into the pelvis difficulties may arise from two chief causes, — uterine inertia, or non-rotation forwards of the chin." After speaking of the treatment for inertia he continues: "The second class are much more important, and may try the resources of the accoucheur to the utmost." It seems to me that it requires much more skill to handle a case where rotation fails than to merely turn the head over while it is still movable above the brim.

Cazeaux, speaking of the treatment of face cases, says: "In the present state of our science the mento-anterior positions should be left to nature, yet does the same rule hold good with regard to posterior ones? In a word, if this last position be clearly recognized before or shortly after the membranes are ruptured, should we not, prior to the engagement of the face, and while the head is still movable, endeavor to convert it into a vertex position, and thus prevent the difficulties that might subsequently arise? If I had to decide under such circumstances I would certainly resolve the question in the affirmative." Has our science advanced sufficiently since his time to warrant us in our undertaking? It seems to me that it has. The great objection in my mind to interfering with cases where the chin is anterior would be that they would be converted into cases with the occiput posterior; but even here, with our present knowledge of the mechanism of these cases, it seems that I should prefer a case of occiput posterior rather than one with the face presenting.

RECENT PROGRESS IN THE CONSTRUCTION OF INSANE HOSPITALS AND MANAGEMENT OF THE INSANE.

BY WALTER CHANNING, M. D.

SPECIAL TRAINING FOR INSANE HOSPITAL ATTENDANTS.

This is a subject which has from time to time attracted considerable attention in this country. It has recently been considered in a more practical manner by A. Campbell Clark, M. B., medical superintendent of the Glasgow District Asylum.[1]

The writer refers to a paper read by Dr. Clouston seven years ago, entitled On the Question of Getting, Training, and Retaining the Services of Good Asylum Attendants, which attracted considerable attention to the subject at the time and has kept it alive since that time. Dr. Clouston has a system of training for new nurses at Morningside in his infirmary, if we are not mistaken.

Dr. Clark's system is rather elaborate, consisting not only of ward instruction, but lectures and examinations as well. The first winter a course of eighteen lectures was given. An abstract of each lecture was written out on the black-board, and the class of attendants was allowed half an hour to copy it. During the winter two written examinations were held. Such questions as How to treat an epileptic in a fit; What risks does an epileptic run; and the treatment of epilepsy, epileptic insanity, bed sores, etc., were among those given. The percentage of failures was smaller than anticipated, and was chiefly among the men, who often were sadly deficient in education, and in some cases lacked ambition. An analysis of the results of this first course of lectures forced Dr. Clark to the conclusion that the lectures were aimed rather too high, but were worth continuing in a more practical form. Ward teaching consisted in the pointing out of symptoms of various forms of disease; indications for vigilance and treatment; and the preparation of brief notes by the attendants on individual cases.

The second course of lectures was followed by the attendants with unabated interest. The subject of one lecture was chiefly a pointing out of the various requisites of a good attendant. Another dwelt on the bodily diseases common to asylums; another on delusions, hallucinations, suicides, homicides; another on asylum accidents, bathing and its dangers, etc. Prizes were offered for the three best essays on hallucinations, each essayist to select three patients as a basis. The examinations were well attended and the results gratifying, and several attendants of both sexes were given first and second class certificates.

Dr. Clark offers some suggestions at the end. One is that British superintendents who are willing to give the system a trial should enter into a combination for two years. The second is that this combination shall merely experiment to the extent of supplying a special training, not compulsory, and shall give class certificates according to efficiency and duration of service. The third is, that a register of attendants, who have received certificates, be printed and circulated at the end of two or three years.

The *American Journal of Insanity*[2] publishes the paper of Dr. Clark, and in addition a letter describing a visit to the Bothwell Asylum, of which Dr. Clark is superintendent.[3] The writer speaks of the smallness of Dr. Clark's asylum, with only 180 patients, but regards this smallness as conducive to a *domesticity* which makes an experiment in the direction of special training of attendants more easy than it would otherwise be.

The last lecture to the attendants had been on Reflex Action, a decapitated frog serving for purposes of illustration. The practical bearing of this principle on disease, epilepsy for example, was explained, and all seemed interested.

Several of the attendants' note-books were examined by the writer, and the extracts which he gives from these show close observation, and are characterized by a freshness not always found in the ordinary insane hospital record book. An attendant's opportunities for observing patients are certainly much better than those of an assistant physician, and it is not unreasonable to assume that data might be obtained in this way which would be of real value if accurately recorded. The intelligence and care requisite for making reliable observations are the qualities usually found in the educated physician, and an absence of them is to be expected in the attendant, but Dr. Clark's method will serve to develop these lacking qualities.

One striking fact brought out by the recorded observations of the attendants was the propensity of women with puerperal mania to burn. A corroboration of this fact the writer found in another asylum.

A novel feature of the Bothwell Asylum was the bringing together of men and women at meals at small tables. The effect was regarded as good. For instance, an old woman "coaxed" the appetite of a boy; a male attendant succeeded in giving food to an obstreperous woman, which the female attendants could not do, and similarly a female attendant gave food to a man, which the male attendants had failed in doing.

Worthy of note at this asylum is a swimming bath thirty-one feet long by eight feet wide, and sloping gradually down from a depth of two and a half feet till a maximum depth of water of four and a half feet is reached. It is lined and floored with glazed tiles. Such a bathing arrangement could be well copied here. If I am not mistaken there have been similar swimming tanks in at least one or two of our own hospitals for the insane, but never on so large a scale or so completely finished. In summer patients would derive both benefit and enjoyment from a plunge in a good swimming bath or tank.

In the conclusion of his letter, the writer states that the veteran psychologist, Dr. W. A. F. Browne, was the first physician, many years ago, to give a course of lectures to asylum attendants.

A SOUTH AMERICAN INSANE HOSPITAL.

Dr. Dreising, of the German navy, has recently[4] given an interesting account of a visit to a lunatic asylum in Uruguay. This institution was begun in 1879, and is as yet only partially completed. The buildings inclose a large garden, which is tastefully laid out. The administration buildings also front on a court-yard laid out as a garden. The buildings are approached by very effective marble steps. The chapel is elaborately finished and very effective.

[1] The Special Training of Asylum Attendants, Journal of Mental Science, January, 1884.
[2] January, 1884.
[3] A Visit to Bothwell Asylum, by G. Alder Blumer, M. D.
[4] All. Zeitschrift f. Psychiatrie, xl., Heft 4, Der Lauder-Irrenhaus von Uruguay.

In the court behind the chapel is the bath-house, which is architecturally the most interesting portion of the buildings. It is built in the form of a half circle. From a corridor which runs the length of it a person looks down on a large cemented basin for *massen-bäder*, or baths all over, as we should say. There are various kinds of complicated douche apparatus in the corridor in separate rooms or *zellen*. Among these are the full douche, the rain douche, the circular douche, and other kinds. Over the whole there is a blue glass roof.

In the rear from this building is one of the buildings devoted to the patients, and in the lower story are the rooms or *zellen* for the excited patients. Each of these rooms has a window which looks directly out on the main recreation ground of the patients. In the upper stories are the patients' sleeping rooms, which have a floor of burnt clay. At night the light comes from gas lights, with blue glass lanterns. The patients take their meals together in a large hall with marble tables.

A small adjoining building is used for private patients, who are divided into three classes, and have rooms accordingly.

The general arrangement of the female wing is similar to that of the male. The Sisters of Charity, who preside over the institution as nurses, are able to make the female patients do considerable work. They make fine lace, and at a recent fair in Buenos Ayres took a prize for silk-spinning. The women are paid for this work, and often get together a little capital to begin life on after leaving the asylum.

The male patients also earn money as bakers, shoemakers, carpenters, cigar makers, and laborers. The cooking for the institution is all done in the institution under the supervision of a sister.

In July, 1882, there were altogether 442 patients in the asylum.

The hospital (medical) staff consisted of a doctor and two medical students in their last semester. Beside these there was one clergyman, one inspector, one secretary, one apothecary, thirteen attendants, ten Sisters of Charity, etc.

INCREASE OF INSANITY.

The recent report[1] of the English Commissioners in Lunacy is of interest in regard to this point. The increase in registered insane persons still continues, having advanced by 1923 since January 1, 1882. The total number of insane persons was 77,196, or one in every 346 of the population. This increase, which seems very large, is largely accounted for by the diminished death-rate, which has been one per cent. less during the last three years than previously. This diminution would make a decrease in three years of 1260.

"Among the private patients the ratio to population has of late years been practically stationary, but the proportion of the pauper class deemed to require care and control continues steadily to rise."

"During the last seven years, however, the increase in the annual occurrence of fresh cases of insanity, pauper and private, as indicated by the yearly admissions of new cases, . . . has not been in excess of the annual increase in the general population."

"It would thus appear that, if we take the total population, the proportion of persons attacked with insanity is not at present on the increase, and that the addition made annually to the total number of certificated insane persons maintained under care and control is due almost entirely to the accumulation of chronic cases."

Such statements as these, coming as they do from such high authority, are of great importance. And, furthermore, they are very encouraging and even surprising to those persons who have thought that insanity was increasing with great rapidity.

The experience of Scotland is even more convincing of the fact that a time may arrive when there will be only a very moderate increase in the number of cases of insanity. The Scottish Commissioners in Lunacy, in their last report,[2] state that with 10,510 insane persons, or twice the number very nearly that we have in Massachusetts, there was an increase of only 149 over the previous year. Only ten of these insane persons were added to the asylum population during the year.

Scotland may certainly be congratulated on this showing, which is so unlike any that we are accustomed to seeing. In this connection it is not out of place to call attention to the high state of perfection to which the system of Scotch lunacy management has arrived. This system shows a diminished death-rate, an increased recovery-rate, and a smaller increase of incurable patients in asylums than other countries. The chief merits of this system seem to be thorough supervision, harmony between the commissioners and medical officers of asylums, absence of restraint, unlocked doors, plenty of occupation, and very frequent visits of patients at home "on probation." Furthermore, however, Scotland is very fortunate in having an unusual number of exceptionably able men engaged at the present time in the care of her insane. As the care of the insane in this country made remarkable progress in the days of Ray, Kirkbride, Brigham, Bell, Earle, Howe, and others, so to-day in Scotland we witness a greater advance than elsewhere in the world, perhaps, from a somewhat similar combination of fortunate circumstances.

The report states, in conclusion, that "after making allowance for the increased population of the country the number of private lunatics in asylums has increased nine per cent. since 1858, and the number of pauper lunatics in asylums and similar establishments has increased eighty-nine per cent. And it is worthy of note that the proportion of pauper lunatics in asylums to the population had decreased last year to 185 per 100,000 from 188, which was the proportion the previous year. This is the first time since the establishment of the Board that we have been able to report a decrease."

In Ireland there were in all institutions for the insane, as well as work-houses, 13,821 insane persons.[3] The increase in the number over 1882 was 377. The inspectors state that these figures do not necessarily indicate a general increase of insanity throughout the country, as they were mostly of a chronic type. The decrease of the population by emigration, which leaves the mentally and physically infirm behind, causes the ratio of the insane to the sane to be higher than it otherwise would.

The latter statement may undoubtedly be a correct

one from the point of view of the Irish administrator of charity at home. As we look at the effect of immigration in this country, however, and more especially in Massachusetts, on the increase of insanity, we see the exact opposite side of the picture. The last report of the Board of Health, Lunacy, and Charity[1] states that the large hospitals have reported on the parentage of the patients admitted, and the aggregate of their statistics is as follows: Whole number of patients classified 3414; of American parentage 1500; Irish parentage 1283; Canadian parentage 181; total of foreign parentage 1914. It will be seen from these figures that only a little more than two fifths of the insane cases, as they arise, are of American parentage. More than one third are of Irish parentage. "This shows, what has long been known from other sources, that there is an undue proportion of insane persons among the recent immigrants who reside in Massachusetts or are here temporarily." A few years hence a majority of our permanent insane hospital population will show a majority of persons of foreign parentage, and almost as many of Irish as of American descent.

In another place[2] the report speaks of an obstacle which has for some time prevented the removal of insane persons, among the recent immigrants, to the country and place from which they came. Most of these immigrants come by English steamships, all of which have surgeons appointed by the English government, and whose decision as to what passengers shall be taken on board is final. They allow many invalid and weak-minded passengers to come to Boston (so the officers of the Board have noticed), but refuse the same persons permission to return again. One case is cited in which an Irish pauper was sent to an insane hospital two weeks after landing, and although the case was a clear one the surgeon of the steamship, to whom application was made to take him home again, refused to receive him. Difficulties of this kind have this year diminished nearly one half the number of insane persons removed from Massachusetts by order of the Board.

Another writer[3] has prepared some statistics, founded on the census of 1880, which also show the large number of insane foreigners in our hospitals and elsewhere. The aggregate number of the insane in the United States in 1880 was 91,997, and of these 26,346 were foreign born, or a little less than one seventh of the population furnished nearly one third of the insane.

(To be concluded.)

— A German physician is trying to get at data of the relation between dampness of house walls and the health of the occupants of the house. He collects samples of the plaster of walls in small glass flasks, and notes their weight before and after drying them in an oven. His experiments in his own neighborhood show that the walls of inhabited rooms, practically regarded as dry, contain about one per cent. of water. This rather curious line of investigation might possibly lead to some practical result, but we imagine that it would take a very elaborate and extended series of observations to enable any opinion of any value to be formed. — *Sanitary Engineer.*

SUFFOLK DISTRICT MEDICAL SOCIETY.

SURGICAL SECTION.

S. J. MIXTER, M. D., SECRETARY.

JANUARY 2, 1884. DR. E. O. OTIS read a paper entitled

A CASE OF CYSTO-PYELITIS, OR PYELO-CYSTITIS, OR CYSTITIS COINCIDENT WITH PYELITIS.[4]

DR. INGALLS spoke of the infrequency of exploratory perineal section in Boston and vicinity, and said it was doubtful if it would have been justifiable in this case, the symptoms of which were very obscure. In case the perinephritic abscess had been aspirated and pus found, a free opening might have been made and the pus evacuated, though the general condition of the patient seems to have been such that the operation would probably have failed to save his life. Dr. Ingalls asked the reader if there was any evidence of tuberculosis found on autopsy. The reader thought not.

DR. CHEEVER said that the beginning of this case somewhat resembled a case of perinephritic abscess in his practice, caused, apparently, by exposure and sleeping on damp ground, in a person of sedentary habits. Its long course is something like pyelitis caused by stricture. The speaker had only once performed perineal section to relieve cystitis, and in that instance no relief followed the operation.

DR. WILLIAM INGALLS reported the following cases:

PREVESICAL CELLULITIS FOLLOWING HERNIOTOMY; PHLEGMONOUS ABSCESS, "SOUS OMBILICALE," IN HEURTAUX SPACE; PERINEPHRITIC ABSCESS.[5]

DR. MIXTER spoke of a case seen by him while interne at the Massachusetts General Hospital, evidently cyst of the urachus, occurring in a boy. On first aspirating the tumor a clear fluid was obtained; suppuration followed, and a free opening was made, and the cavity thoroughly drained. The tumor disappeared, and the patient recovered. Dr. Mixter also mentioned a case of umbilical abscess, the cause of which proved to be a solid mass, made up of epidermal cells, concentrically arranged, which, on dilating the small opening present in the umbilicus, was found and removed.

DR. GEORGE G. HAYWARD mentioned a somewhat similar case of umbilical abscess, in which were found several grains of wheat, apparently the cause of the abscess.

DR. BURRILL spoke of a case of perinephritic abscess occurring in a boy four months after a blow on the back. When first seen he had been confined to his bed for four weeks, and there was a large fluctuating tumor in the right loin. An incision being made at this point, a large amount of pus was evacuated, and a finger, on being introduced into the incision, could be passed upward to the kidney and downward nearly to Poupart's ligament.

DR. CHEEVER remarked that sub-muscular abscesses were much more frequent than others in the abdominal walls, being often caused by violence. It is in the space of Retzius that the bladder is aspirated in cases of retention, the operation almost never being followed by unpleasant results. Dr. Cheever mentioned the

[4] See page 290 of this number of the JOURNAL.
[5] See page 289 of this number of the JOURNAL.

case of an old man with retention from enlarged prostate. Irregular practitioners had endeavored to catheterize him, but, failing, had aspirated at the usual point above the pubes. The sharp aspirator needle was left in for four days, at the end of which time the speaker first saw the patient. At this time there was an ulcerated opening into the bladder with urinary infiltration and suppuration in the space of Retzius extending down along the sides of the bladder. Perineal section was done, but the patient died the next day. This was the only case ever seen by the speaker which might be called pre-vesical abscess.

SECTION FOR OBSTETRICS AND GYNÆCOLOGY.

C. P. STRONG, M. D., SECRETARY PRO TEM.

NOVEMBER 21ST. The meeting was called to order at eight o'clock. DR. F. MINOT in the chair.

DR. SWIFT presented a paper entitled

A CASE OF FACE PRESENTATION, WITH SOME REMARKS ON THE TREATMENT OF THIS CLASS OF CASES.[1]

DR. DOE inquired as to the size of the pelvis in the case reported, and asked if this abnormal presentation was not commonly found in cases of roomy pelvis, because of the relative difference in the size of the head as compared with the pelvis. He alluded to the fact that in cases left entirely to nature there was often no delay until the head came well down to the perinæum, and referred to two cases in his own practice where nature terminated the labor, one, a primipara, in twelve hours, the other, a multipara, in five hours, in both cases the delay occurring during the passage of the head over the perinæum. Should he meet with such a case again he would etherize and attempt to bring down the vertex.

DR. SWIFT said in his case, so far as he could determine, the pelvis was of normal size. He thought it quite likely that the malposition would occur in a roomy pelvis.

DR. COBB inquired as to the necessity of employing ether.

DR. SWIFT thought that it was not an absolute necessity in every case, but was certainly a great aid.

In reply to a question by Dr. McDonald, Dr. Swift said that in the case reported the diagnosis was made very early, but, of course, in this regard cases would vary.

DR. MCDONALD inquired as to the advisability of employing forceps or version instead of the operation recommended.

DR. SWIFT said that high forceps would be necessary, and the passage of the head would not be made any easier by their employment, while as to version there was the increased danger to the mother of a severe operation, and to the child the added danger of a breech presentation.

DR. PARKS asked the reader if he should ever employ forceps, having in view especially the tendency of the displacement to recur after reposition.

DR. SWIFT said that if the diagnosis was not made until the face was too firmly engaged to allow of any change in its position he should treat the case as he would any presentation of the head, and apply forceps if there were delay in the advance, although the application to the face was more difficult than to the vertex. He also stated that one of the most essential points of the proceeding he advised was, after bringing down the occiput, to hold it in its proper place until the head was so firmly engaged that the malposition could not be reproduced.

DR. HAYWARD spoke of a case he had seen in Vienna, where the patient was left unaided for twenty-four hours until the os was fully dilated, and then a modification of the axis traction forceps was used. The child was alive, but there was a tremendous caput succedaneum, which afterwards suppurated. In this case hot baths were employed to start up the pains. In another case of the same presentation, complicated by a contracted pelvis and partial placenta prævia, version was performed, and one foot brought down to plug the os, and the case was left to nature.

DR. KINGMAN inquired whether the reader would employ version or forceps in a case where the vertex could not be brought down and the chin was posterior.

DR. SWIFT replied, version. He said that the maneuver he described, to be successful, required that not only must the vertex be brought down, but the position of the body must be changed, as at the time it was in opisthotonos, and this would react on the head, and tend to reproduce the malposition. This was readily accomplished by pushing with the outside hand on the breech in such a way as to double the child up, when the head naturally tended to a position of flexion, which was desired.

In reply to Dr. Lombard, Dr. Swift said he should attempt to rectify the position in every case, whether the chin were anterior or posterior, and even if the maternal pelvis seemed roomy.

DR. LOMBARD thought authorities differed from the reader, advising that a case where everything was progressing well should be left to nature.

DR. SWIFT said that as the trouble almost invariably came when the head was low in the pelvis, and was so firmly engaged that any manipulation was extremely difficult, he certainly should endeavor in every case seen while the head was still above the brim and movable, to substitute the normal vertex presentation for the abnormal face, the more especially because the plan he suggested offered no danger, or very little, either to the mother or child, and occupied but a short time.

DR. BUNDY asked as to the frequency of face presentations, which the reader stated statistics gave as one in 250 labors.

DR. MINOT stated that when by this maneuver or by any other which gave equal safety to the child an operation such as version was avoided, it seemed to him well to adopt it, and thus free the mother from the dangers of a more serious operation. As between version and high forceps he considered version the more dangerous operation.

DR. DOE also preferred high forceps as affording better prospects for the child.

DR. SWIFT said the profession were now agreeing that for use in high-forceps cases some form of the axis traction forceps was most desirable, and especially referred to Simpson's modification of Tarnier's.

DR. HAYWARD said that in Braun's wards in Vienna a modification of Tarnier's instrument was used, and in Speath's wards Simpson's modification, and that in

[1] Vide page 293 of this number of the JOURNAL.

both places it was claimed that by their use craniotomy was in many cases avoided.

DR. BUNDY asked as to the principal cause of danger to the woman in version, which DR. SWIFT said was shock.

DR. PARKS asked as to the danger of displacing the placenta.

DR. SWIFT thought this danger was very small, as was also that arising from twisting of the cord about the child.

DR. OSGOOD asked as to the danger to the child in version.

DR. SWIFT said it was the same as in all breech cases.

DR. OSGOOD advised the more frequent use of forceps to the after-coming head without permitting any delay.

DR. MCDONALD asked the reader where, in a case left to nature, if the uterus ruptured, he should expect to find the seat of the rupture.

DR. SWIFT said at or near the junction of the cervix and body.

DR. DOE spoke of a series of reported cases of rupture, where it was found that the rent began at the external os and extended longitudinally through the cervix.

THE NEW YORK ACADEMY OF MEDICINE.

THE PUBLICATION OF PAPERS.

AT a stated meeting held March 6th a communication was received from the Council, in which it was recommended that every paper read before the Academy should be presented to the Council, and, after its approval by that body, be immediately published at the expense of the Academy, as well as inserted in the volume of Transactions published at the end of the year. After the President, Dr. Barker, had explained that this would not debar any Fellow from publishing his paper in a medical journal instead, if he preferred to do so, the recommendation was adopted.

A LIBERAL DONATION.

The Council also reported that Dr. Horace P. Farnham, for several years the treasurer of the Academy, had sent his check for $1000 to aid in paying off the $7000 mortgage still remaining on the Academy's building, and recommended that the donor should be enrolled among the Benefactors of the Academy. Dr. Farnham was then elected a Benefactor, and, after some remarks by the President the check was presented to Dr. F. A. Castle, treasurer of the Board of Trustees, who stated that he had recently received $670 for the same purpose. On motion of Dr. Hubbard it was voted to pay off $2000, and have the mortgage reduced to $5000.

THE DETECTION OF ALBUMEN IN URINE.

DR. GEORGE B. FOWLER read a paper entitled The Detection of Albumen in Urine, with a Review of the Methods Recently Advanced. The paper was illustrated throughout by practical demonstrations, and after a few introductory remarks in regard to the various kinds of albumen, he proceeded to speak first of heat as a test. If any specimen of urine contained as much as nine per cent. of albumen, he said, a solid clot would be formed on the application of heat. Neither acid albumen or alkali albumen, which were both derived albumens, instead of native, were, however, coagulable by heat; but if sufficient acid were added to neutralize the alkali albumen and sufficient alkali to neutralize the acid albumen, the precipitate would take place. It was important, therefore, to see that the urine to be tested was neither strongly acid or strongly alkaline. He had found that the smallest quantity of albumen that could be detected by heat was .2 per cent.

The next agent that he mentioned was nitric acid, which he said was capable of detecting .1 per cent. of albumen. It was important, as a rule, to boil the urine before adding acids. Ferrocyanide of potassium, in connection with citric or acetic acid, afforded an equally delicate test, and the acidulated brine method, suggested by Dr. Roberts, of Manchester, was also a good one. The smallest quantity of albumen that could be detected by it, however, was 1. per cent. (In all his experiments Dr. Fowler employed urine of a specific gravity of 1022.)

Of the new tests the one that had attracted most attention was picric acid, for the use of which the profession was indebted to Dr. Johnson, of London. It was employed in a saturated solution, about seven grains to the ounce of boiling water. The solution would stain the hands of a deep yellow color, but it was not corrosive, and could be readily washed off. After Dr. Johnson communicated this test to the Clinical Society Dr. Ralph discovered that the picric acid also had the effect of precipitating peptones when they were present in the urine; so that there was seen to be a possible source of error in connection with it. It was afterwards found, also, that if quinine was present in the urine (as was very apt to be the case when this drug was being taken in any considerable quantities), or if the urates were in excess, a precipitate would be caused by picric acid. In consequence of these facts, Dr. Johnson made a series of experiments to eliminate such sources of error, and found that the precipitates mentioned were cleared up by heat, though they were liable to return again when the liquid cooled. Picric acid, therefore, though a very delicate test, had to be used with care. When very minute traces of albumen were to be detected, it was advisable to use it according to Heller's method with nitric acid. Equal bulks of the acid solution and urine were employed; and if albumen were present the precipitate would be seen as a delicate ring between the two fluids.

Dr. Owen, of London, had proposed two excellent tests. The first was tungstate of sodium with an acidulated solution, acetic or citric acid being employed. The other, which was the most delicate test that had as yet been discovered, was potassio-mercuric iodide with an acid, and it was capable of detecting .01 per cent. of albumen. It was not original with him, but had first been mentioned by a French observer. In devising many of the later tests the aim had been to secure a practicable and convenient method for bedside use, and Dr. Owen seemed to have hit upon this in the invention of his test papers. One set of slips of bibulous paper were dipped in a saturated solution of potassio-mercuric iodide, and another in a saturated solution of citric acid. They were then allowed to dry; after which they were ready for use at any time. When the test was to be made, a slip of each kind was placed in the bottom of a test tube, and the urine poured on them; when, if albumen were present, a precipitate would be seen to be formed as the papers dissolved. On account of the ex-

treme delicacy of this test, however, it was not adapted for use in life insurance examinations, since Dr. Fowler had found that a trace, at least, of albumen was discovered by it in almost every specimen of urine to which he applied it. Whether this presence of a minute quantity of albumen in the urine of such a large proportion of individuals were due to any diseased condition or not yet remained to be determined. The following table shows the smallest amount of albumen that was detected by the various tests mentioned in the experiments made by Dr. Fowler:—

Heat	.2 per cent.
Mineral acids	.1 per cent.
Picric acid	.1 per cent.
Acidulated brine	1. per cent.
Ferrocyanide of potassium	.1 per cent.
Tungstate of sodium	.1 per cent.
Potassio-mercuric iodide	.01 per cent.

After a few remarks by the Chair, the discussion of the paper was opened by DR. E. DARWIN HUDSON, who said that his interest in the detection of albumen in the urine was chiefly of a practical nature. In the current of medical literature for the past few years he had watched very carefully for new light on the subject; but the more that he had learned in regard to the later tests proposed the more had he become disposed to adhere to the old-established methods so long familiar to the profession. After listening to Dr. Fowler's paper he could only say that he was still further confirmed in this conclusion. For the use of the busy practitioner he believed that heat and nitric acid were still the most trustworthy tests that could be used; although he had no doubt that even with these there was need of the explicit instructions which had been set forth in the paper. It was too common a practice among physicians to apply nitric acid before heating the urine, and he thought it was a good rule always to ascertain the reaction of the fluid with litmus paper, and then bring it to as nearly a neutral condition as possible by the addition of an alkali or acid as required, before proceeding to test for albumen. In any case where the symptoms were of a doubtful character it was a great mistake to dismiss the examination of the urine without resorting to the microscope if no albumen could be detected, even after repeated testings. In speaking of the objections to some of the new tests for albumen Dr. Hudson said that in the case of picric acid too much manipulation was required to avoid possible errors to make it of permanent practical value, and the test papers of Dr. Owen seemed altogether too delicate. For all clinical purposes he believed the old methods were sufficiently accurate.

DR. GASPAR GRISWOLD agreed with Dr. Hudson that the picric acid test was objectionable on account of the number of possible errors connected with it. It might be of interest from a chemical point of view to detect a minute quantity of albumen such as was shown by the potassio-mercuric iodide test, but the question was, Is it desirable, from a clinical point of view, to find these very small quantities? Albuminuria was not at the present day regarded as necessarily such a serious condition as had formerly been the case. The old tests were probably sufficient for all clinical purposes, and under ordinary circumstances heat was the most reliable if the urine was clear. It was his own practice to employ two test tubes, both of which he took care to see were perfectly clean. The urine in one was boiled, while that in the other was not, and after the boiling the two specimens were carefully compared against a black background. Afterwards he was in the habit of resorting, in addition, to Heller's cold nitric acid test. When the urine to be examined was not clear he added a fourth part of *liquor potassæ*, and filtered. If the tests for albumen were refined too much he thought they lost their practical value.

PROF. CHARLES DOREMUS thought also that cleanliness of test tubes and clear urine aided the physician more than very refined tests. When Heller's method was employed, after the addition of an alkali to render the urine clear, however, there was danger of disturbance by the ebullition of a little gas from the action of the acid, and, therefore, if it was necessary to add an alkali it was better to employ the test of ferrocyanide of potassium with acetic acid. Meta-phosphoric acid was also an excellent test.

DR. MUNN spoke of the great importance of having a properly shaded light. The way in which he arranged this was as follows: The background against which the test tube was held was a piece of black pasteboard, which was fastened immediately below a window provided with a dark shade. The shade was pulled all the way down, and the proper light was secured by holding the bottom of the shade a short distance out from the window-sill. In this way it was sometimes possible to find traces of albumen which would otherwise have escaped observation.

DR. MAXWELL made some remarks in reference to the use of the various tests, more particularly those of picric acid and tungstate of sodium, and said that he seldom or never trusted to one test alone, usually resorting to three or four different ones. Incidentally he stated that he had as yet failed to find a specimen of peptonuria. In regard to the clinical significance of these later tests, if in any case a little albumen was detected, but, after careful and repeated microscopic examinations, no casts could be found, the albumen would not be regarded as of any consequence.

DR. FOWLER then said that the object of the paper was simply to bring about such a discussion as had resulted. He was convinced that reliance should never be placed on one test alone. Heat was that which was usually tried first, but after failing to detect albumen by means of heat (or for the purpose of confirming its presence thus indicated) he thought it well to go on with some of the other tests, and he could not agree with Dr. Griswold that there was no use of investigating unexplored fields in this connection. It was only by means of these later and more delicate tests that it could be determined whether a certain amount of albumen was not a normal constituent of the urine.
